

AE054

UNO KIT STARTER KIT

RFID LEARNING SUITE

V1.0.23.10.26

Preface

Our Company

KUONGSHUN Electronic Company is a supplier and manufacturer of electronic components, it is committed to board and starter kit for Arduino, Raspberry PI, Smart Robot Car, 3D printer. It is also a collection of scientific research, design, production, maintenance and sales of high-tech enterprises, in the field of automation with professional standards and mature technology, we rapid rise in the field of foreign trade.

Relying on technology and development, continuing to provide users with high-tech products, is our constant pursuit. Fully introduction of foreign advanced technology to enhance the value of our products.

Company gains users' praise for supplying first-class quality product and superb technical services, has now become the first choice of domestic and international procurement company.

Official Website: <https://www.kuongshun.com>

Our Tutorial

This course and learning kit is designed for 8+ children and teenagers to Arduino-compatible boards, shields, sensors, and components. If you just start making with Arduino, this kit could provide the knowledge and components to create innovative projects.

Through this kit, beginners can:

1. Learn how to use the Arduino control board. The Arduino board is the brain of electronic projects. Mastering its usage is essential for learning electronics and programming.
2. Learn the basics of C language. Arduino uses a simplified C/C++ programming language to control electronic components. This kit will teach you the basics to get started.

3. Learn the usage of each electronic component. Components like LED, resistors, sensors, and motors are the building blocks of electronic projects. You will learn what each component does and how to use it.
4. Make many projects to practice your skills. From simple LED blinking to advanced robotics, the projects in this kit cover a wide range. Doing projects is the best way to learn.
5. Advance to create your own works. After learning the basics, you can get creative by combining components in new ways. Some students have created innovative projects and even applied for patents.
6. Build a solid foundation for future learning. The knowledge and experience you gain here will benefit your future study in electronics, programming, and robotics. The Arduino kit is a great start for the exciting technology journey ahead!

In summary, this Arduino learning kit is designed for beginners to get started with basic electronics and programming in a fun, hands-on way. By following the tutorial, students of all ages can learn skills that will unlock their potential in technology and innovation.

Customer Service

As a continuous and fast growing technology company we keep striving our best to offer you excellent products and quality service as to meet your expectation and you can reach out to us by simply drop a line at info@kuongshun.cn We look forward to hearing from you and any of your critical comment or suggestion would be much valuable to us.

And any of problems and questions you have with our products will be promptly replied by our experienced engineers within 12 hours (24hrs during holiday)

we pursue the policy of "progressive, Truth, Rigorous and Unity", keeping innovation, paying attention of technology as the core, committing to quality and putting customer's satisfaction on the priority, dedicated to provide you with the most cost-effective high-tech products and attentive service.

Packing list

 Controller Board 1PCS	 1602 I2C LCD 1PCS	 65 Jumper Wire 1PCS	 830 Tie-Points Breadboard 1PCS	 Stepper Motor 1PCS
 ULN2003 Stepper Motor Driver Board	 DS1302 RTC Real Time Clock Module 1PCS	 Remote 1PCS	 Rc522 RFID Module 1PCS	 USB Cable 1PCS

Lesson 0 Installing IDE

Introduction

The Arduino Integrated Development Environment (IDE) is the software side of the Arduino platform.

In this lesson, you will learn how to setup your computer to use Arduino and how to set about the lessons that follow.

The Arduino software that you will use to program your Arduino is available for Windows, Mac and Linux. The installation process is different for all three platforms and unfortunately there is a certain amount of manual work to install the software.

STEP 1: Go to <https://www.arduino.cc/en/Main/Software> and find below page.

The screenshot shows the Arduino 1.8.0 download page. On the left is the Arduino logo (an infinity symbol with a minus and plus sign). To its right, the text reads: "ARDUINO 1.8.0", "The open-source Arduino Software (IDE) makes it easy to write code and upload it to the board. It runs on Windows, Mac OS X, and Linux. The environment is written in Java and based on Processing and other open-source software.", "This software can be used with any Arduino board. Refer to the Getting Started page for Installation Instructions." On the right side of the page, there are links for "Windows Installer", "Windows ZIP file for non admin install", "Windows app" (with a "Get" button), "Mac OS X 10.7 Lion or newer", "Linux 32 bits", "Linux 64 bits", "Linux ARM", "Release Notes", "Source Code", and "Checksums (sha512)".

ARDUINO 1.8.0

The open-source Arduino Software (IDE) makes it easy to write code and upload it to the board. It runs on Windows, Mac OS X, and Linux. The environment is written in Java and based on Processing and other open-source software.

This software can be used with any Arduino board. Refer to the [Getting Started](#) page for Installation Instructions.

Windows Installer
Windows ZIP file for non admin install
Windows app [Get](#)
Mac OS X 10.7 Lion or newer
Linux 32 bits
Linux 64 bits
Linux ARM
[Release Notes](#)
[Source Code](#)
[Checksums \(sha512\)](#)

The version available at this website is usually the latest version, and the actual version may be newer than the version in the picture.

STEP2: Download the development software that is compatible with the operating system of your computer. Take Windows as an example here.

Click *Windows Installer*.

Support the Arduino Software

Consider supporting the Arduino Software by contributing to its development. (US tax payers, please note this contribution is not tax deductible). Learn more on how your contribution will be used.

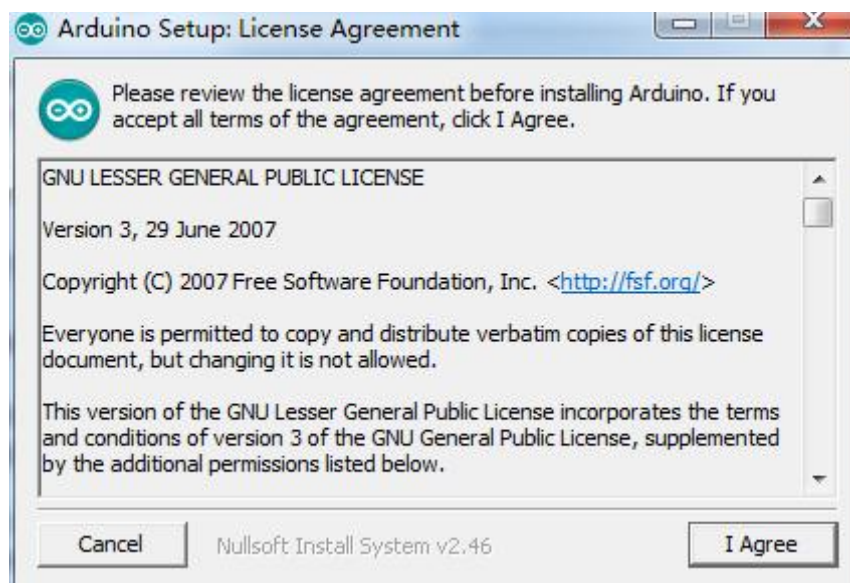

Click *JUSTDOWNLOAD*.

Also version 1.8.0 is available in the material we provided, and the versions of our materials are the latest versions when this course was made.

 `arduino-1.8.0-linux32.tar.xz`
 `arduino-1.8.0-linux64.tar.xz`
 `arduino-1.8.0-macosx.zip`
 `arduino-1.8.0-windows.exe`
 `arduino-1.8.0-windows.zip`

Installing Arduino (Windows)

Install Arduino with the exe. Installation package.

 `arduino-1.8.0-windows.exe`

Click *I Agree* to see the following interface

Click Next

You can press Browse... to choose an installation path or directly type in the directory you want.

Click *Install* to initiate installation

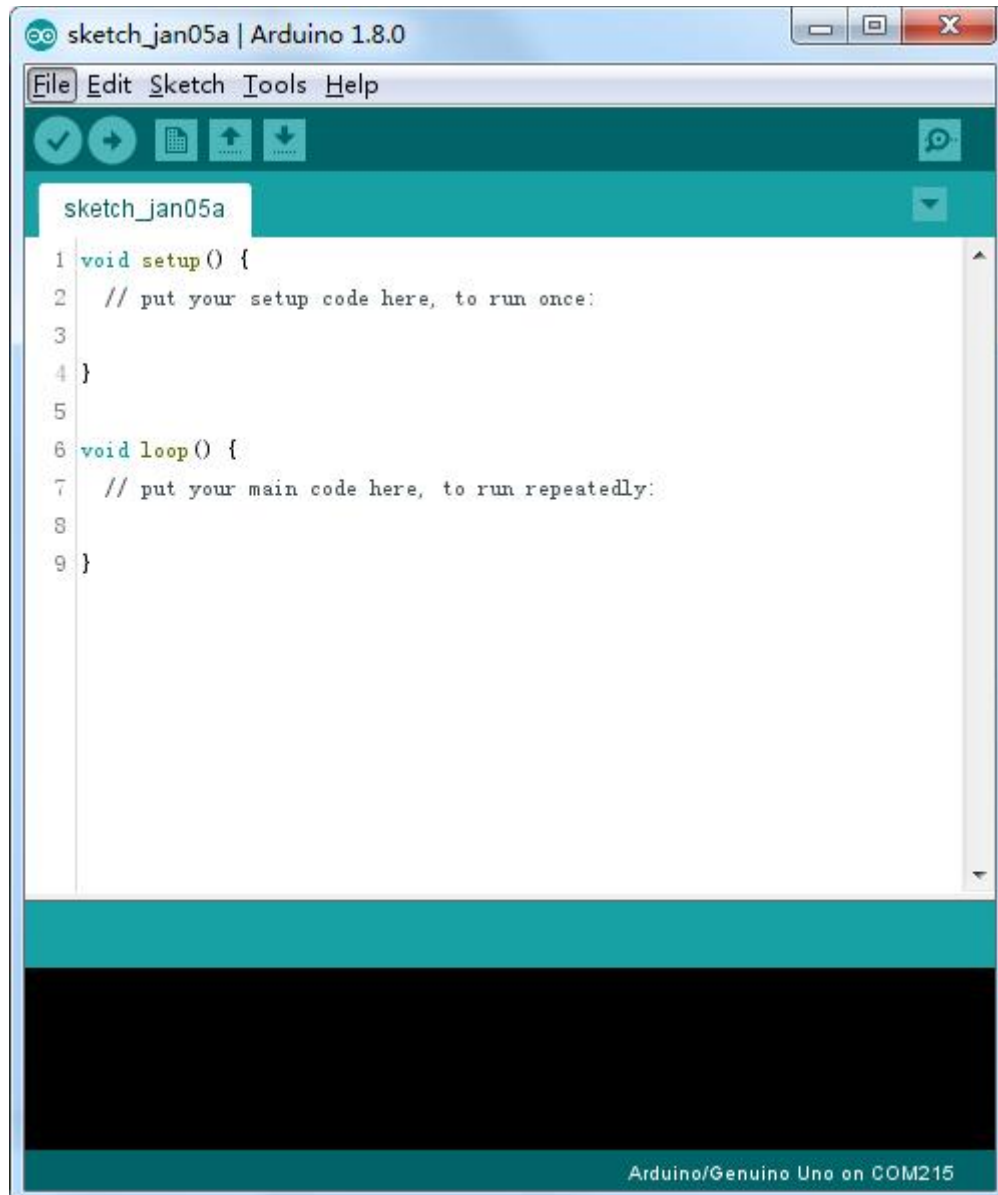

Finally, the following interface appears, click *Install* to finish the installation.

Next, the following icon appears on the desktop

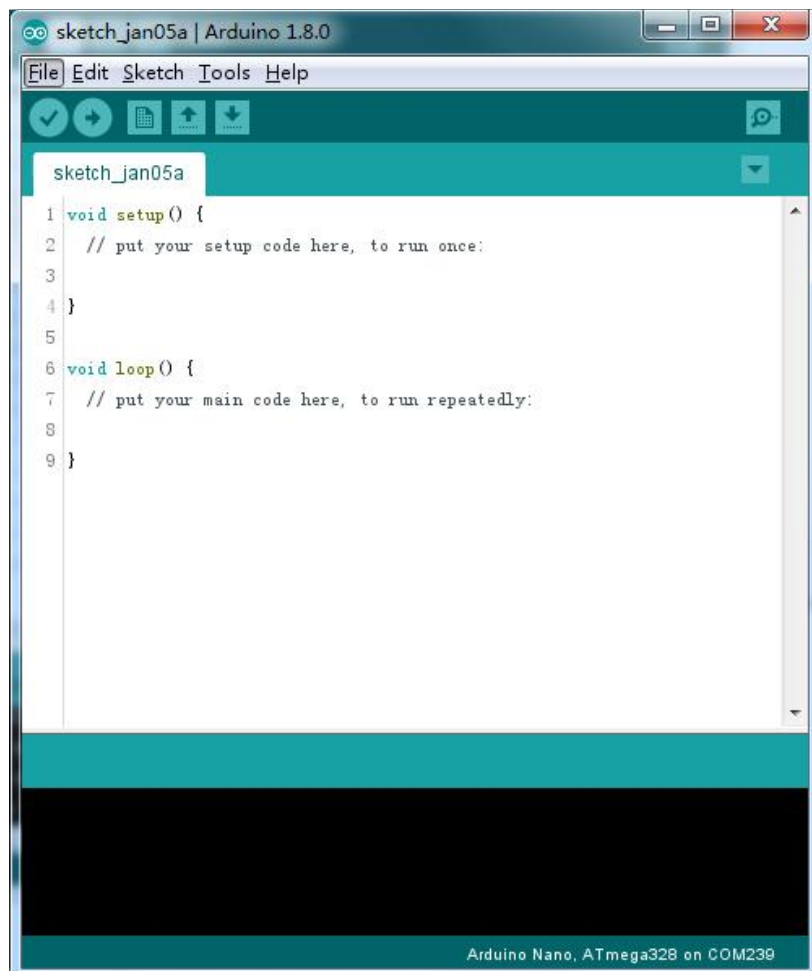

Double-click to enter the desired development environment

You may directly choose the installation package for installation and skip the contents below and jump to the next section. But if you want to learn some methods other than the installation package, please continue to read the section.

Unzip the zip file downloaded, Double-click to open the program and enter the desired development environment

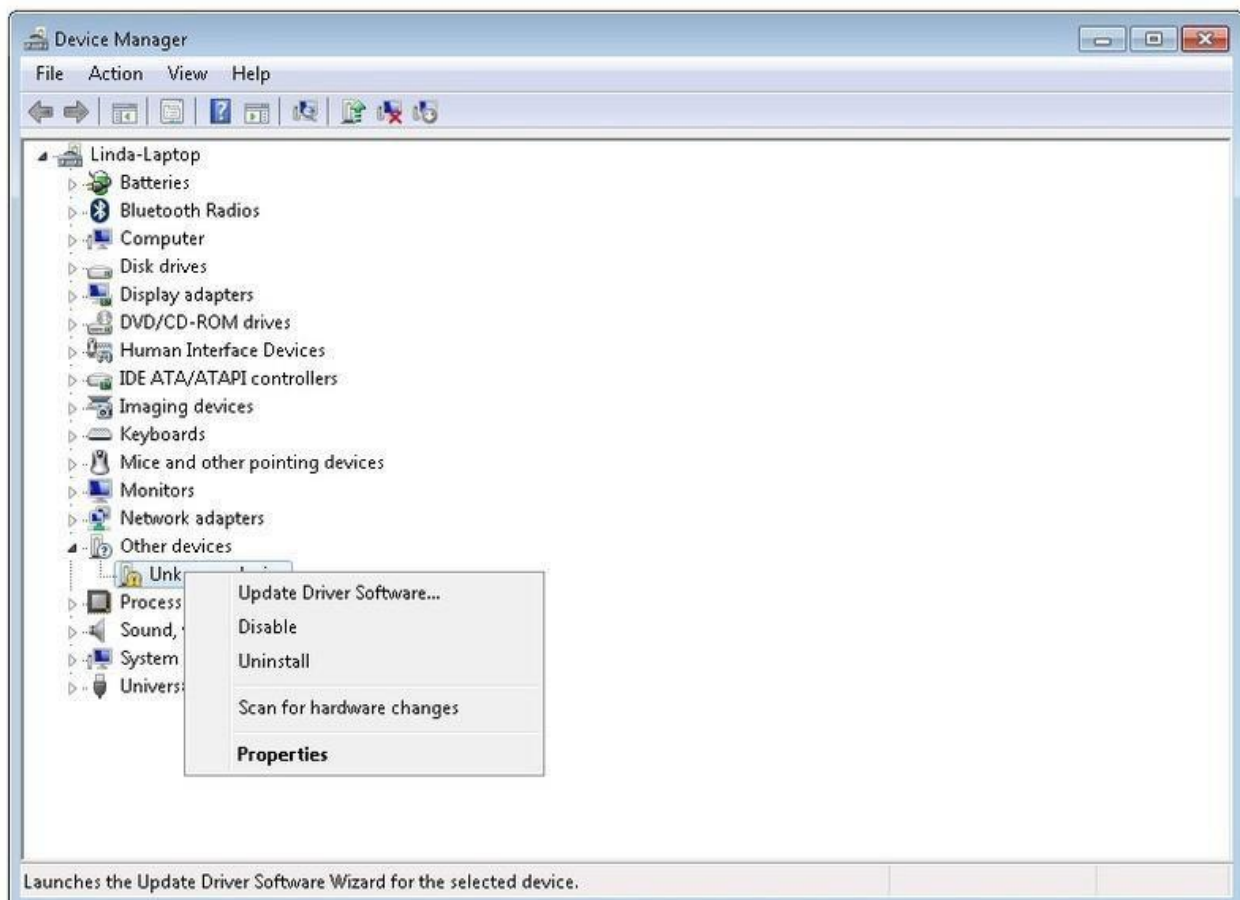

However, this installation method needs separate installation of driver.

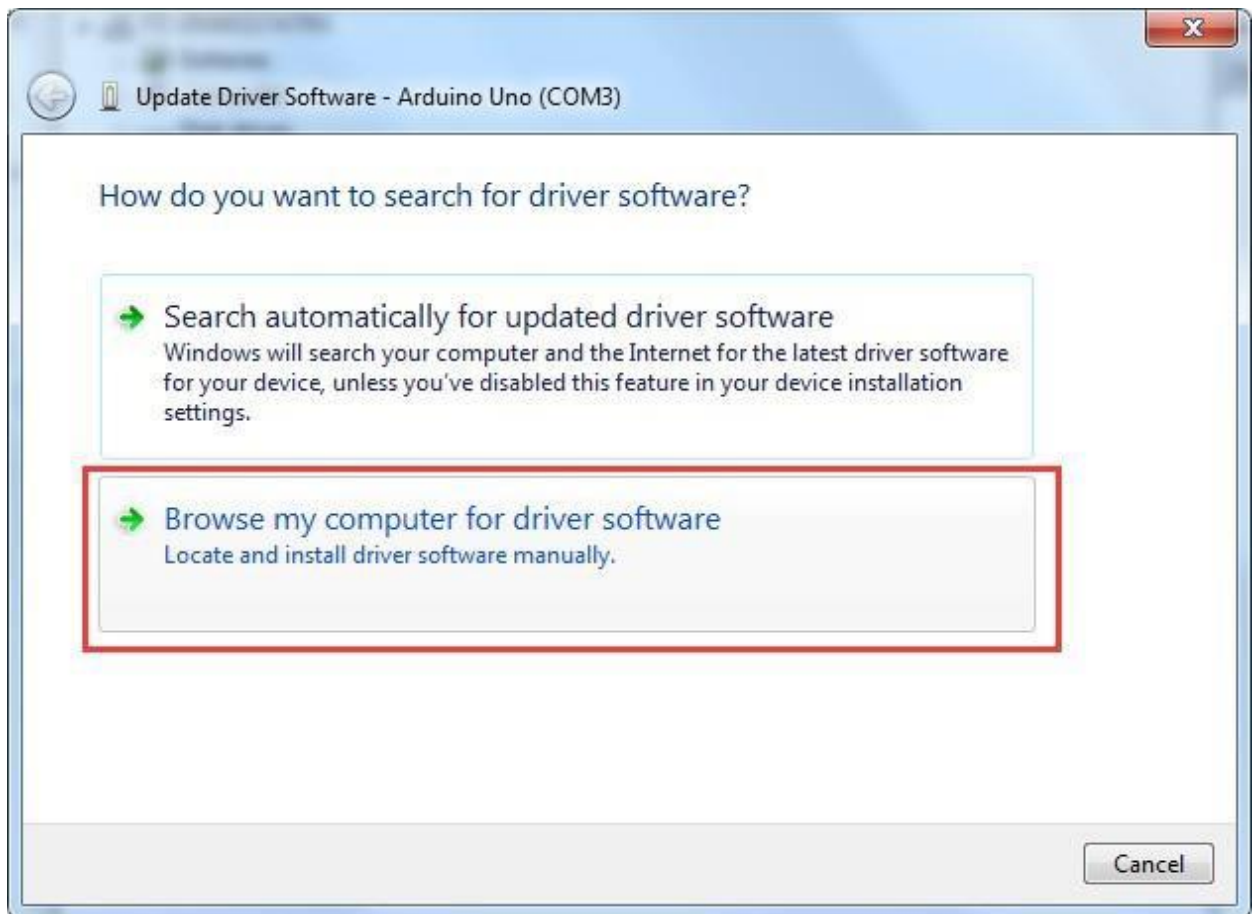

The Arduino folder contains both the Arduino program itself and the drivers that allow the Arduino to be connected to your computer by a USB cable. Before we launch the Arduino software, you are going to install the USB drivers.

Plug one end of your USB cable into the Arduino and the other into a USB socket on your computer. The power light on the LED will light up and you may get a 'Found New Hardware' message from Windows. Ignore this message and cancel any attempts that Windows makes to try and install drivers automatically for you.

The most reliable method of installing the USB drivers is to use the Device Manager. This is accessed in different ways depending on your version of Windows. In Windows 7, you first have to open the Control Panel, then select the option to view Icons, and you should find the Device Manager in the list.

Under 'Other Devices', you should see an icon for 'unknown device' with a little yellow warning triangle next to it. This is your Arduino.

Right-click on the device and select the top menu option (Update Driver Software...). You will then be prompted to either 'Search Automatically for updated driver software' or 'Browse my computer for driver software'. Select the option to browse and navigate to the X\arduino1.8.0\drivers.

Click 'Next' and you may get a security warning, if so, allow the software to be installed. Once the software has been installed, you will get a confirmation message.

Windows users may skip the installation directions for Mac and Linux systems and jump to Lesson 1. Mac and Linux users may continue to read this section.

Installing Arduino (Mac OS X)

Download and Unzip the zip file, double click the Arduino.app to enter Arduino IDE; the system will ask you to install Java runtime library if you don't have it in your computer. Once the installation is complete you can run the Arduino IDE.

Installing Arduino (Linux)

You will have to use the make install command. If you are using the Ubuntu system, it is recommended to install Arduino IDE from the software center of Ubuntu.

 `arduino-1.8.0-linux32.tar.xz` `arduino-1.8.0-linux64.tar.xz`

TIPS: If you have problems in installing the drivers, please refer to the UNO R3, MEGA, NANO DRIVER FAQ.

 UNO R3, MEGA, NANO DRIVER FAQ

Lesson 1 Add Libraries and Open Serial Monitor

Installing Additional Arduino Libraries

Once you are comfortable with the Arduino software and using the built-in functions, you may want to extend the ability of your Arduino with additional libraries.

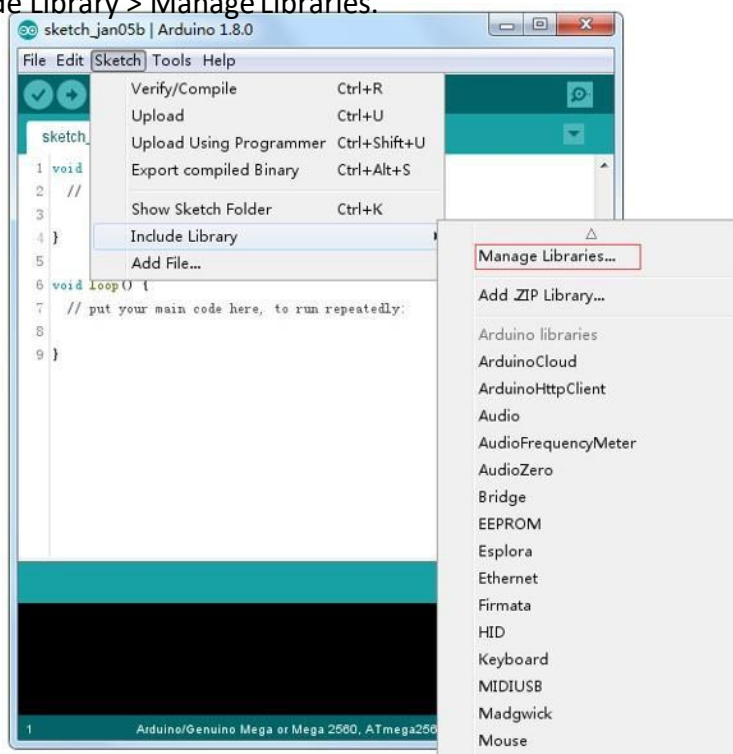

What are Libraries?

Libraries are a collection of code that makes it easy for you to connect to a sensor, display, module, etc. For example, the built-in LiquidCrystal library makes it easy to talk to character LCD displays. There are hundreds of additional libraries available on the Internet for download. The built-in libraries and some of these additional libraries are listed in the reference. To use the additional libraries, you will need to install them.

How to Install a Library

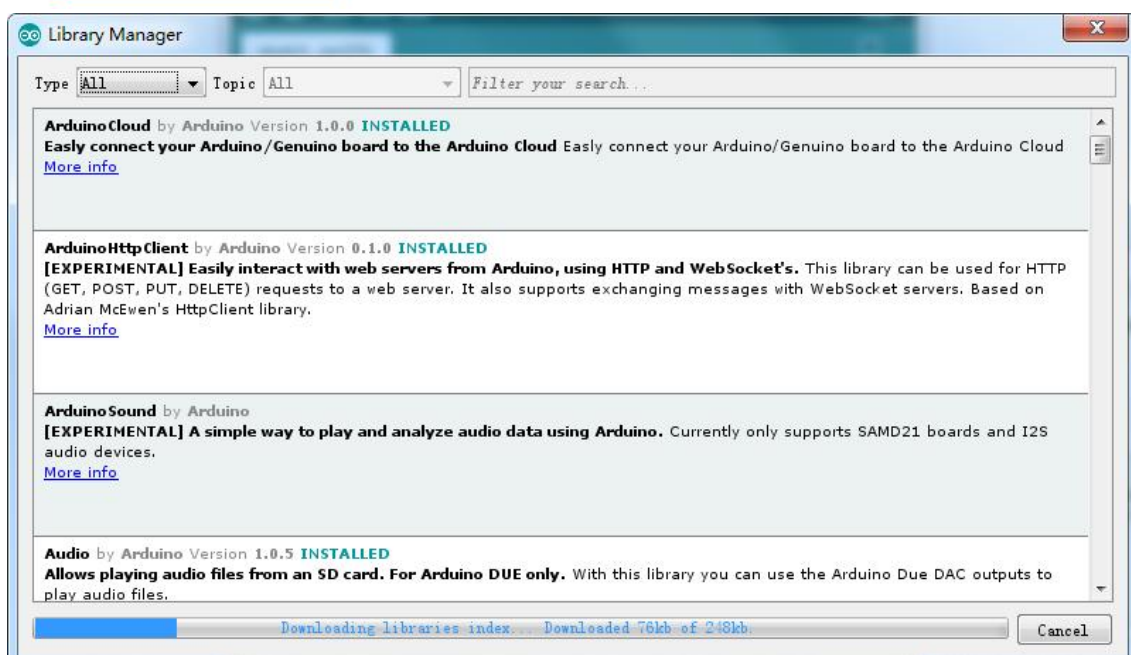

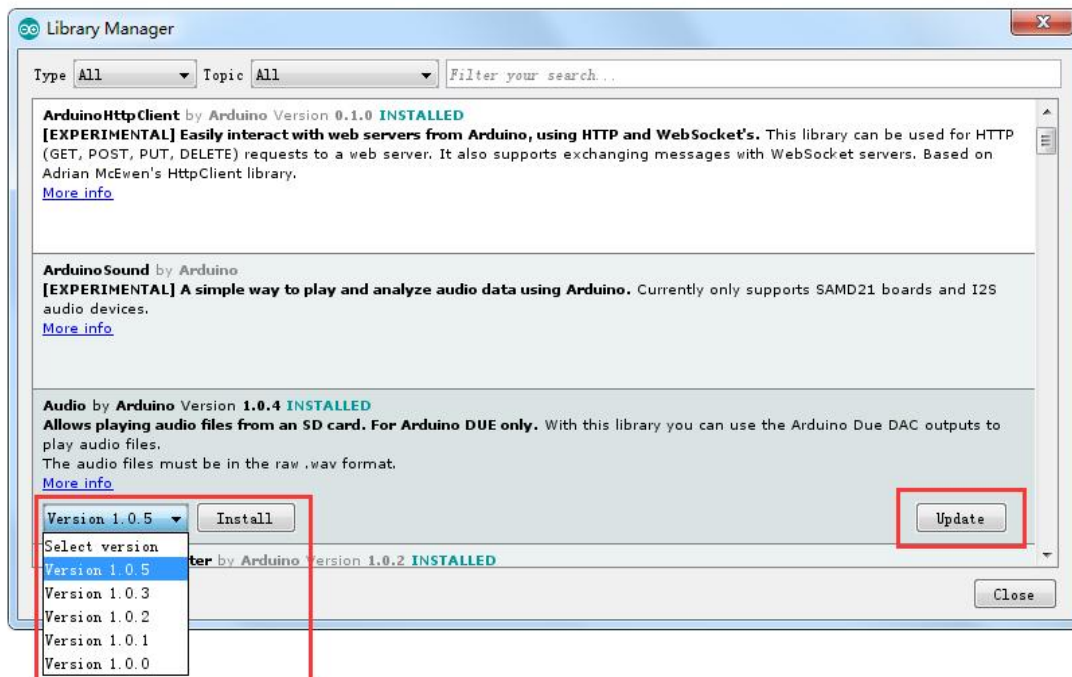

Using the Library Manager

To install a new library into your Arduino IDE you can use the Library Manager (available from IDE version 1.8.0). Open the IDE and click to the "Sketch" menu and then **Include Library > Manage Libraries...**

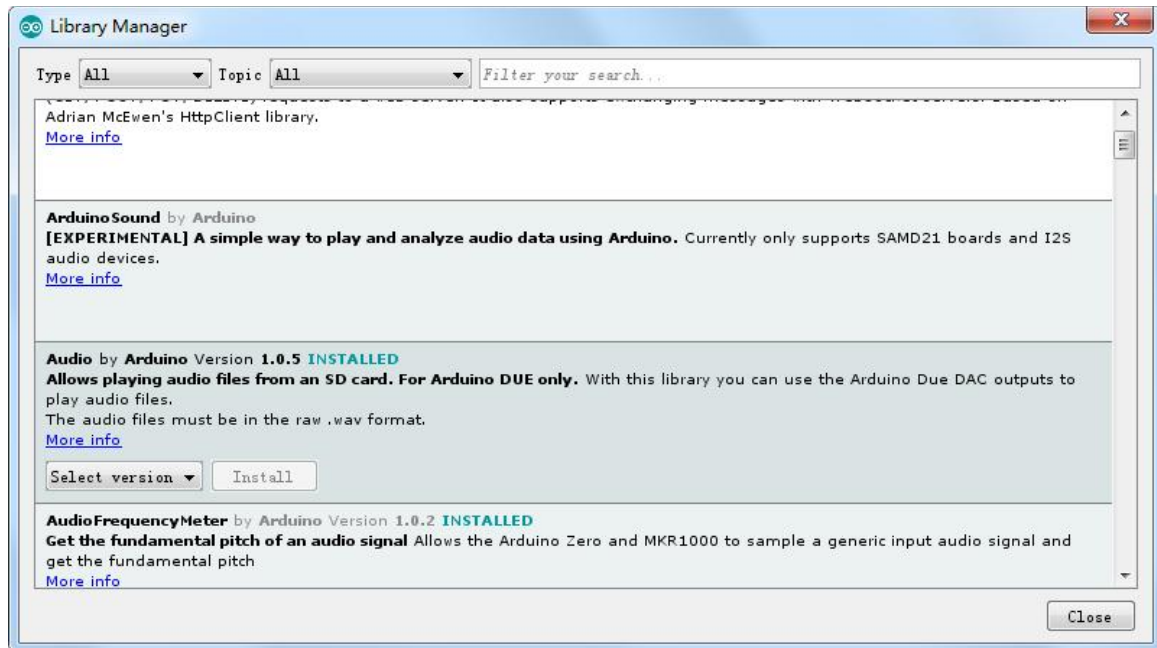

Then the library manager will open and you will find a list of libraries that are already installed or ready for installation. In this example we will install the Bridge library. Scroll the list to find it, then select the version of the library you want to install. Sometimes only one version of the library is available. If the version selection menu does not appear, don't worry: it is normal.

There are times you have to be patient with it, just as shown in the figure. Please refresh it and wait.

Finally click on install and wait for the IDE to install the new library. Downloading may take time depending on your connection speed. Once it has finished, an Installed tag should appear next to the Bridge library. You can close the library manager.

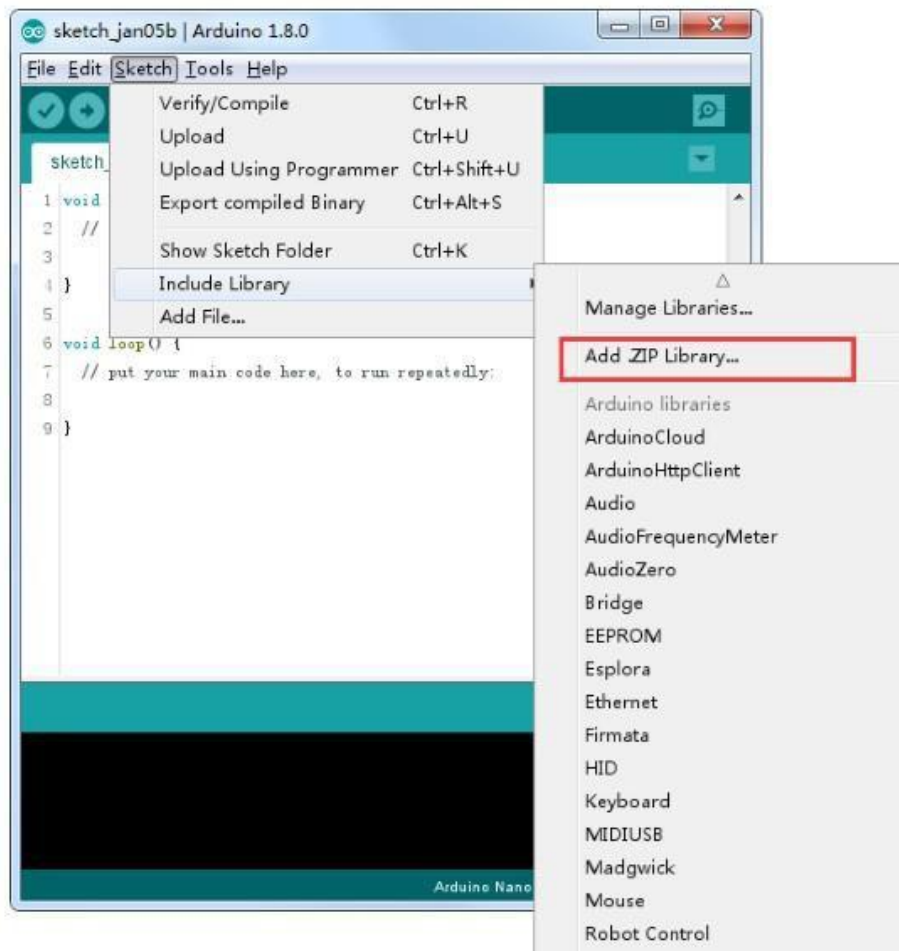

You can now find the new library available in the Include Library menu. If you want to add your own library open a new issue on [Github](#).

Importing a .zip Library

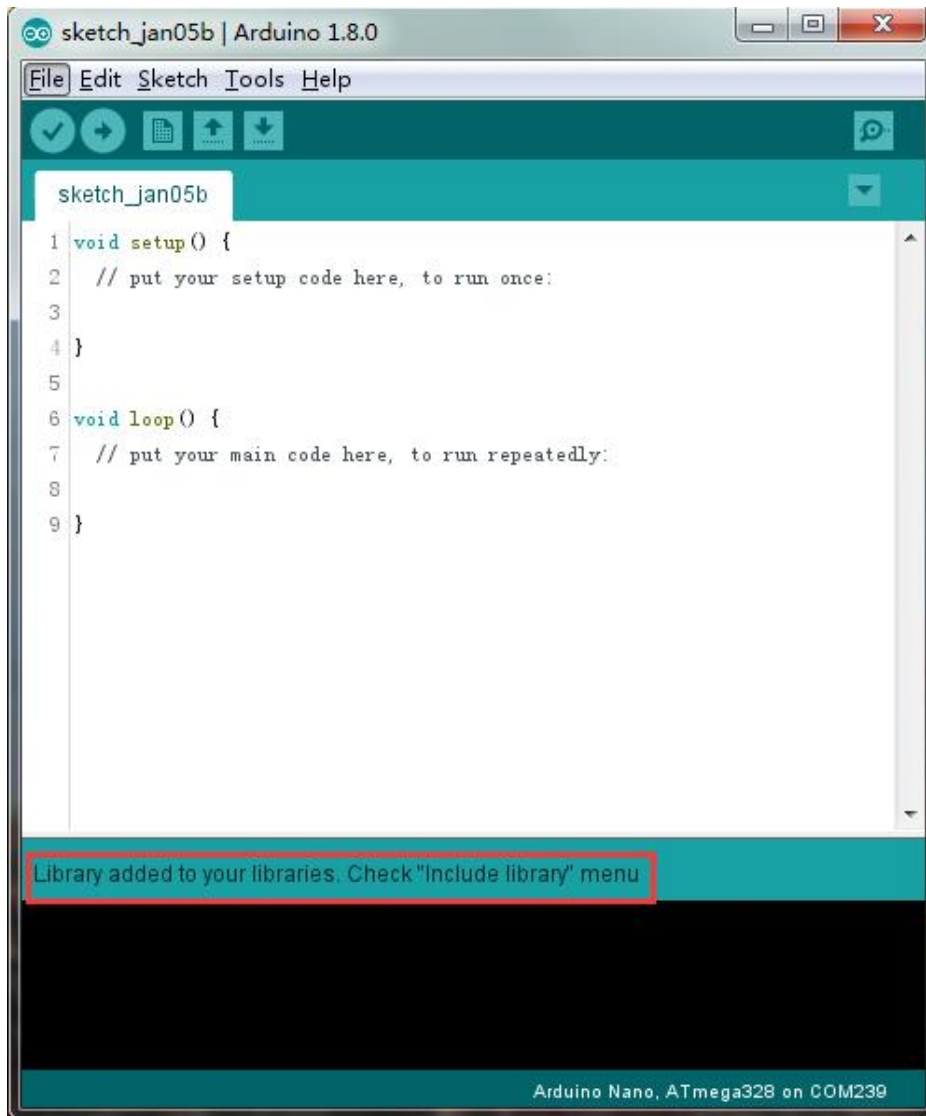

Libraries are often distributed as a ZIP file or folder. The name of the folder is the name of the library. Inside the folder will be a .cpp file, a .h file and often a keywords.txt file, examples folder, and other files required by the library. Starting with version 1.0.5, you can install 3rd party libraries in the IDE. Do not unzip the downloaded library, leave it as is.

In the Arduino IDE, navigate to Sketch > Include Library. At the top of the drop down list, select the option to "Add .ZIPLibrary".

You will be prompted to select the library you would like to add. Navigate to the .zip file's location and open it.

Return to the Sketch > Import Library menu. You should now see the library at the bottom of the drop-down menu. It is ready to be used in your sketch. The zip file will have been expanded in the libraries folder in your Arduino sketches directory. **NB:** the Library will be available to use in sketches, but examples for the library will not be exposed in the File > Examples until after the IDE has restarted.

Those two are the most common approaches. MAC and Linux systems can be handled likewise. The manual installation to be introduced below as an alternative may be seldom used and users with no needs may skip it.

Manual installation

To install the library, first quit the Arduino application. Then uncompress the ZIP file containing the library. For example, if you're installing a library called "ArduinoParty",

uncompress ArduinoParty.zip. It should contain a folder called ArduinoParty, with files like ArduinoParty.cpp and ArduinoParty.h inside. (If the .cpp and .h files aren't in a folder, you'll need to create one. In this case, you'd make a folder called "ArduinoParty" and move into it all the files that were in the ZIP file, like ArduinoParty.cpp and ArduinoParty.h.)

Drag the ArduinoParty folder into this folder (your libraries folder). Under Windows, it will likely be called "My Documents\Arduino\libraries". For Mac users, it will likely be called "Documents/Arduino/libraries". On Linux, it will be the "libraries" folder in your sketchbook.

Your Arduino library folder should now look like this (on Windows):

My Documents\Arduino\libraries\ArduinoParty\ArduinoParty.cpp

My Documents\Arduino\libraries\ArduinoParty\ArduinoParty.h

My Documents\Arduino\libraries\ArduinoParty\examples

or like this (on Mac and Linux):

Documents/Arduino/libraries/ArduinoParty/ArduinoParty.cpp

Documents/Arduino/libraries/ArduinoParty/ArduinoParty.h

Documents/Arduino/libraries/ArduinoParty/examples

....

There may be more files than just the .cpp and .h files, just make sure they're all there. (The library won't work if you put the .cpp and .h files directly into the libraries folder or if they're nested in an extra folder. For example:

Documents\Arduino\libraries\ArduinoParty.cpp and

Documents\Arduino\libraries\ArduinoParty\ArduinoParty\ArduinoParty.cpp won't work.)

Restart the Arduino application. Make sure the new library appears in the Sketch->Import Library menu item of the software. That's it! You've installed a library!

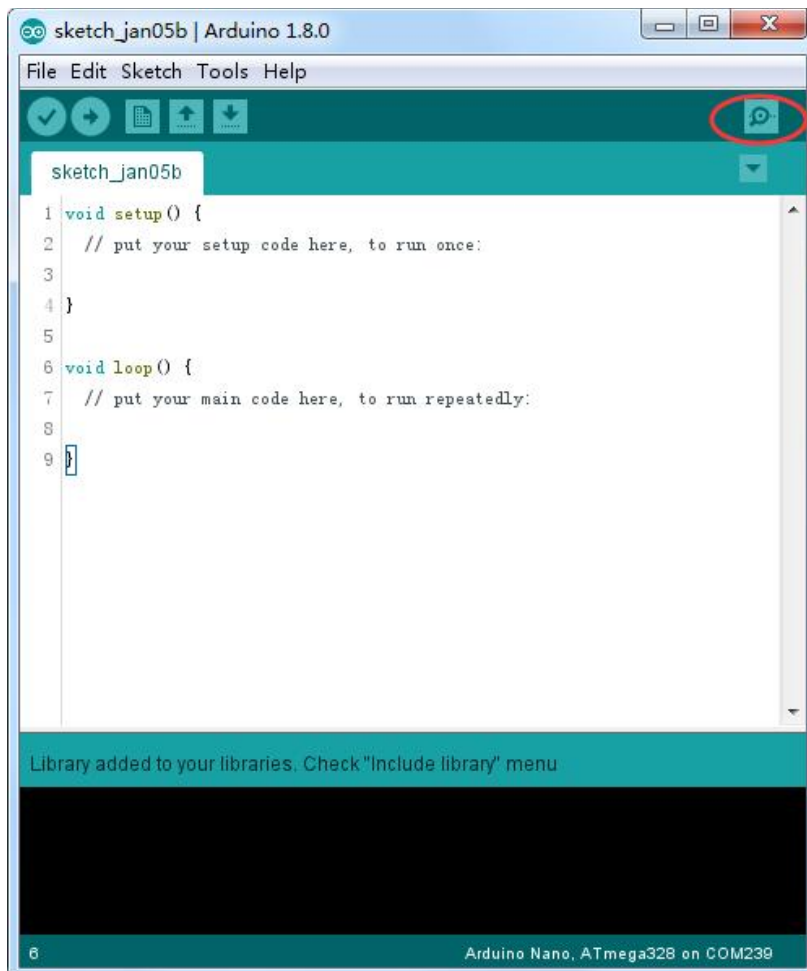

Arduino Serial Monitor (Windows, Mac, Linux)

The Arduino Integrated Development Environment (IDE) is the software side of the Arduino platform. And, because using a terminal is such a big part of working with

Arduinos and other micro controllers, they decided to include a serial terminal with the software. Within the Arduino environment, this is called the Serial Monitor.

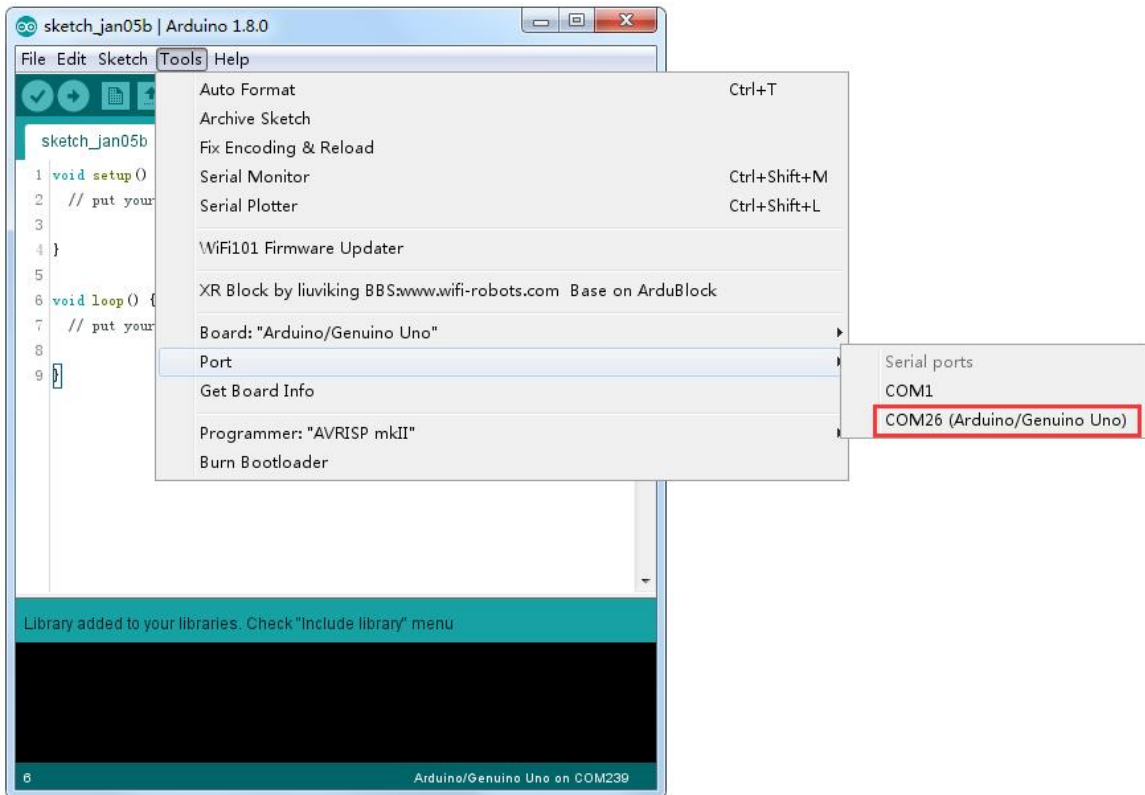

Making a Connection

Serial monitor comes with any and all version of the Arduino IDE. To open it, simply click the Serial Monitor icon.

Selecting which port to open in the Serial Monitor is the same as selecting a port for uploading Arduino code. Go to Tools -> Serial Port, and select the correct port.

Tips: Choose the same COM port that you have in Device Manager.

Once open, you should see something likethis:

Settings

The Serial Monitor has limited settings, but enough to handle most of your serial communication needs. The first setting you can alter is the baud rate. Click on the baud rate drop-down menu to select the correct baud rate. (9600 baud)

Last, you can set the terminal to Autoscroll or not by checking the box in the bottom left corner.

Pros

The Serial Monitor is a great quick and easy way to establish a serial connection with your Arduino. If you're already working in the Arduino IDE, there's really no need to open up a separate terminal to display data.

Cons

The lack of settings leaves much to be desired in the Serial Monitor, and, for advanced serial communications, it may not do the trick.

Lesson 2 Blink

Overview

In this lesson, you will learn how to program your UNO R3 controller board to blink the Arduino's built-in LED, and how to download programs by basic steps.

Component Required:

(1)x KUONGSHUN UNO R3

Principle

The UNO R3 board has rows of connectors along both sides that are used to connect to several electronic devices and plug-in 'shields' that extends its capability. It also has a single LED that you can control from your sketches. This LED is built onto the UNO R3 board and is often referred to as the 'L' LED as this is how it is labeled on the board.

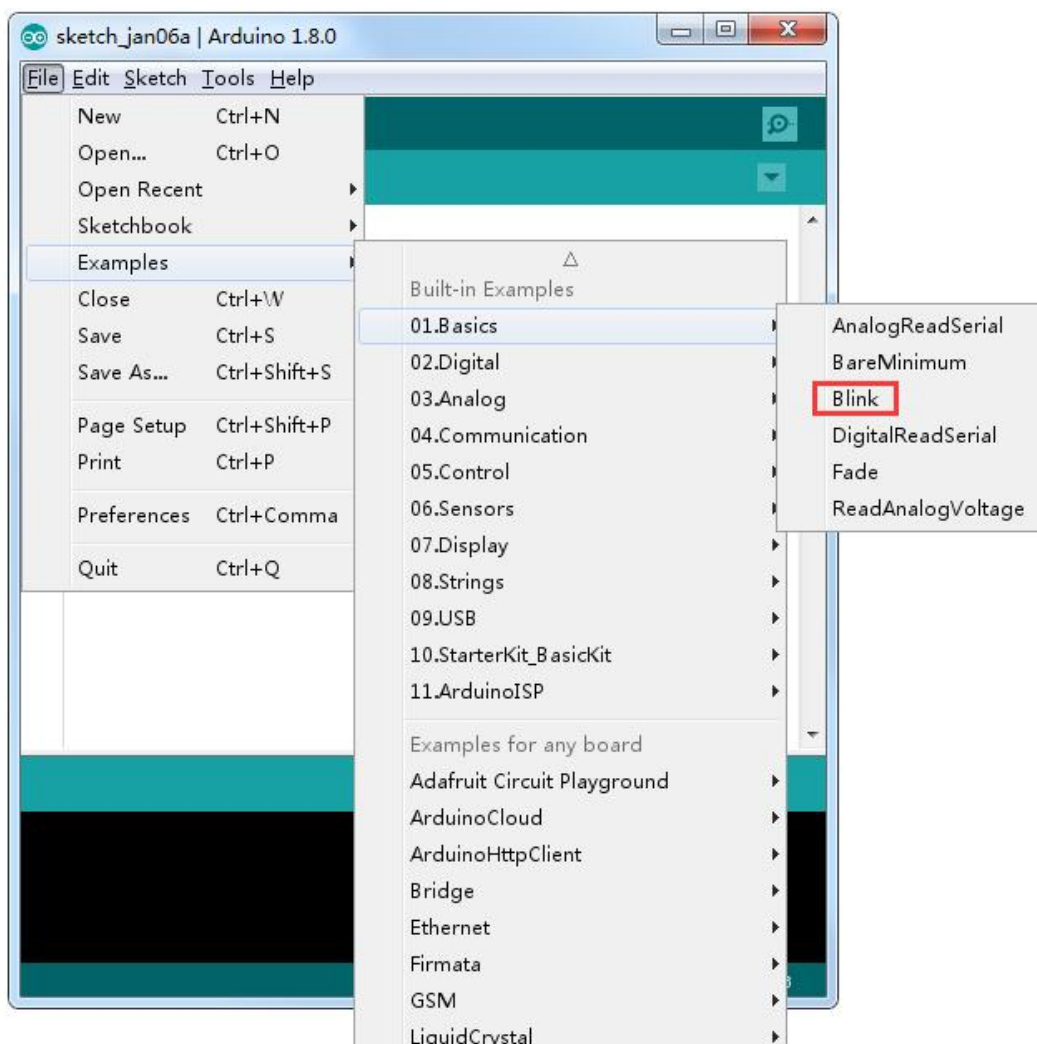

You may find that your UNO R3 board's 'L' LED already blink when you connect it to a USB plug. This is because the boards are generally shipped with the 'Blink' sketch pre-installed.

In this lesson, we will reprogram the UNO R3 board with our own Blink sketch and then change the rate at which it blink.

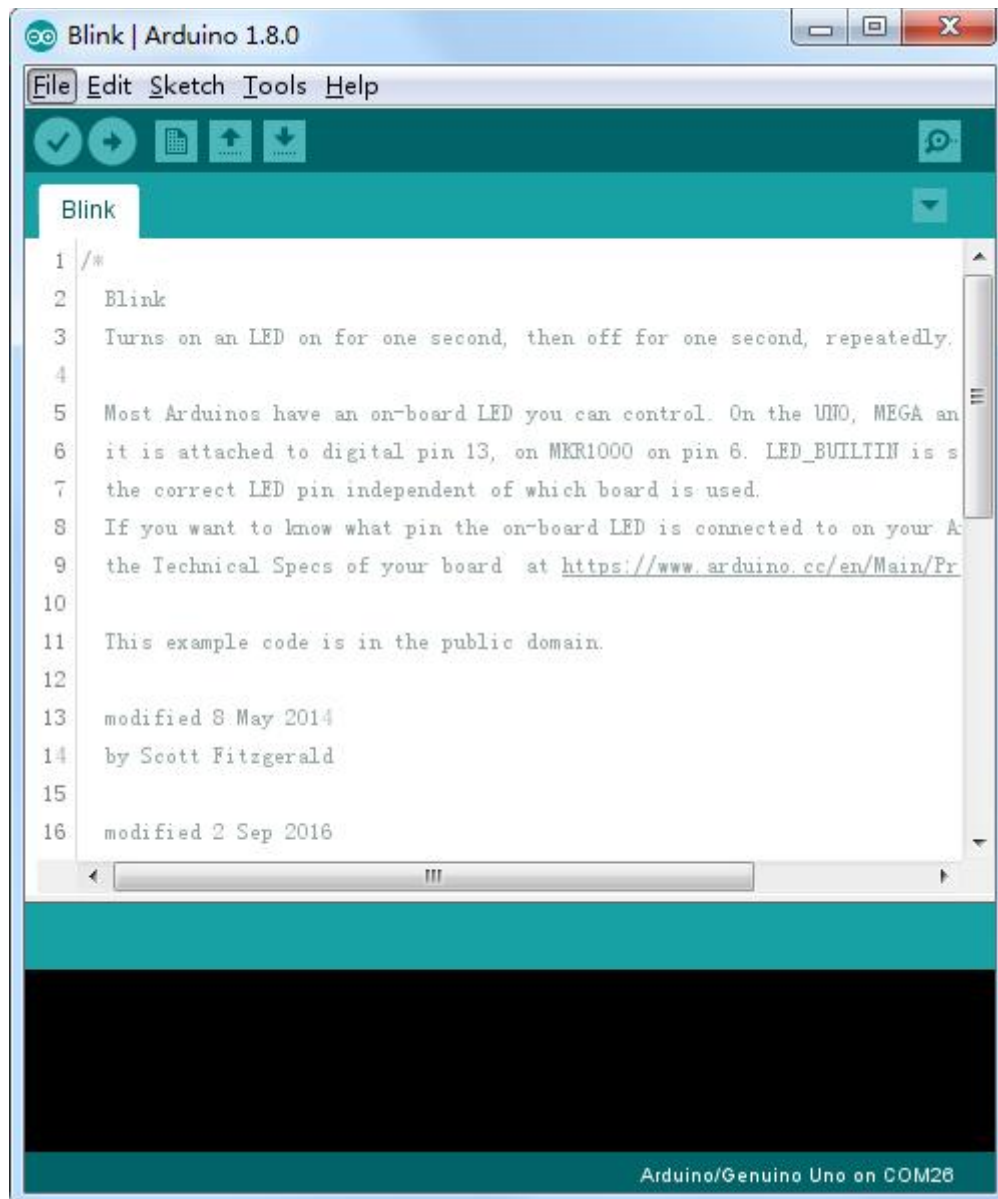

In Lesson 0, you set up your Arduino IDE and made sure that you could find the right serial port for it to connect to your UNO R3 board. The time has now come to put that connection to the test and program your UNO R3 board.

The Arduino IDE includes a large collection of example sketches that you can load up and use. This includes an example sketch for making the 'L' LED blink.

Load the 'Blink' sketch that you will find in the IDE's menu system under File > Examples > 01.Basics

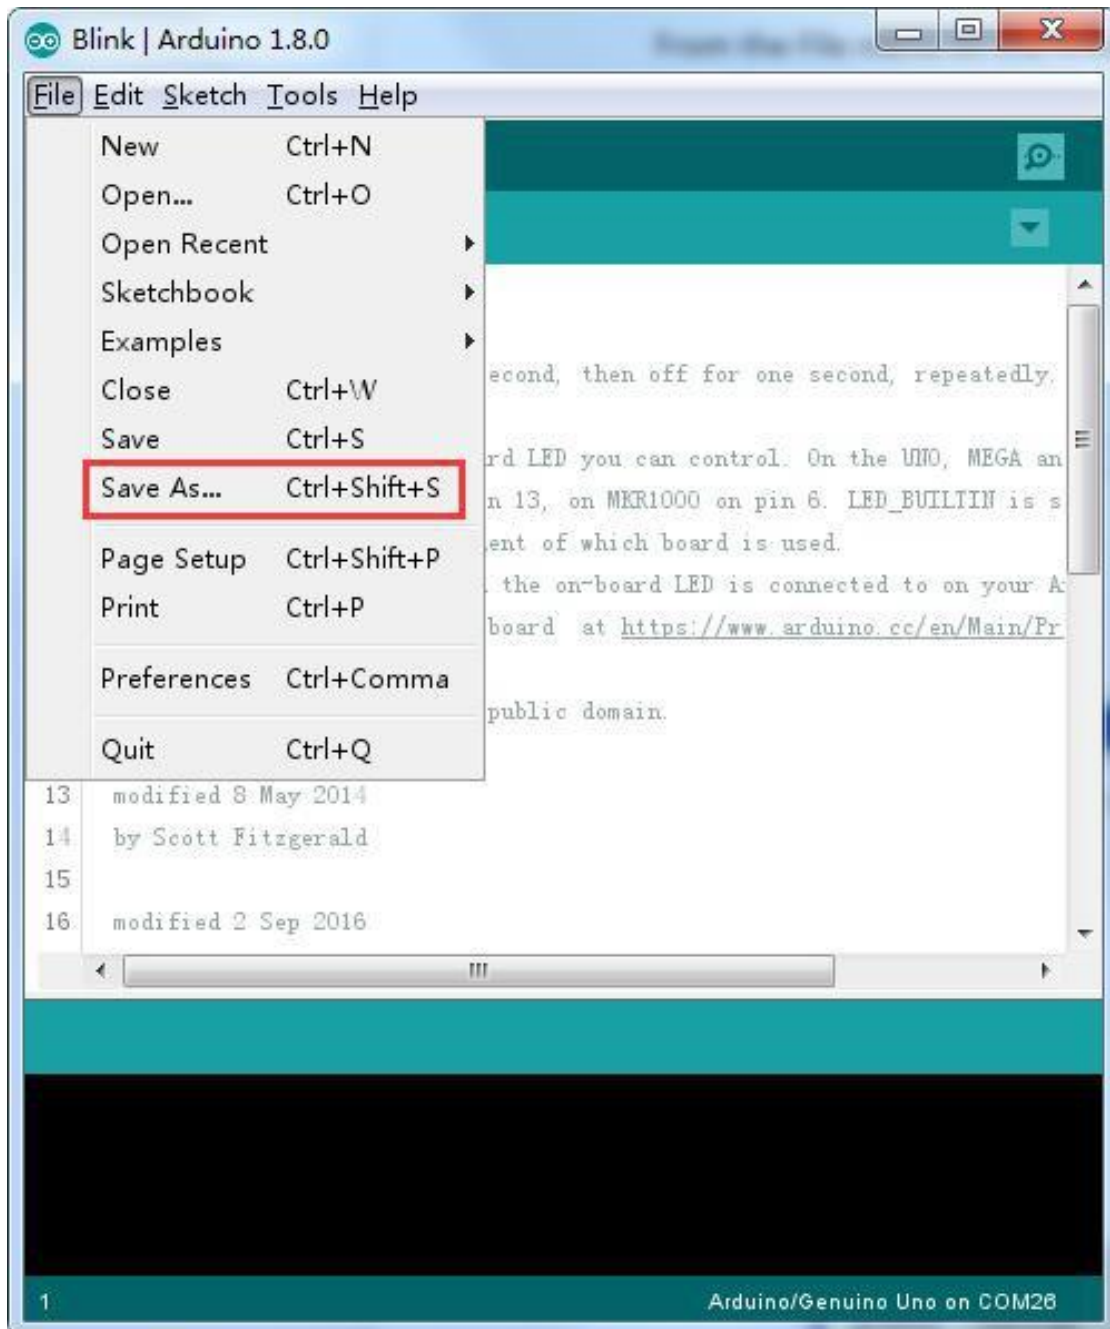

When the sketch window opens, enlarge it so that you can see the entire sketch in the window.

The example sketches included with the Arduino IDE are 'read-only'. That is, you can upload them to an UNO R3 board, but if you change them, you cannot save them as the same file.

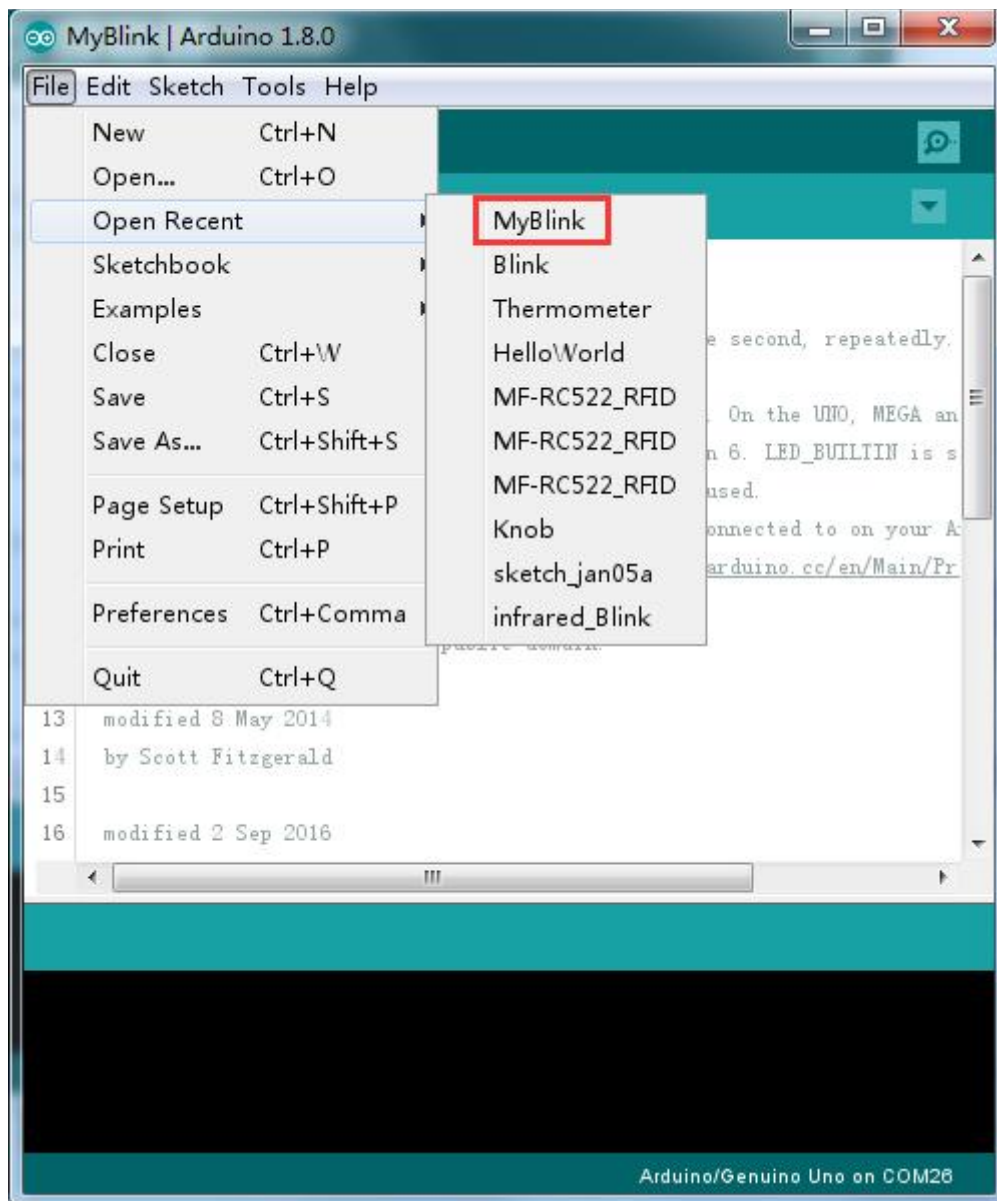

Since we are going to change this sketch, the first thing you need to do is save your own copy.

From the File menu on the Arduino IDE, select 'Save As..' and then save the sketch with the name 'MyBlink'.

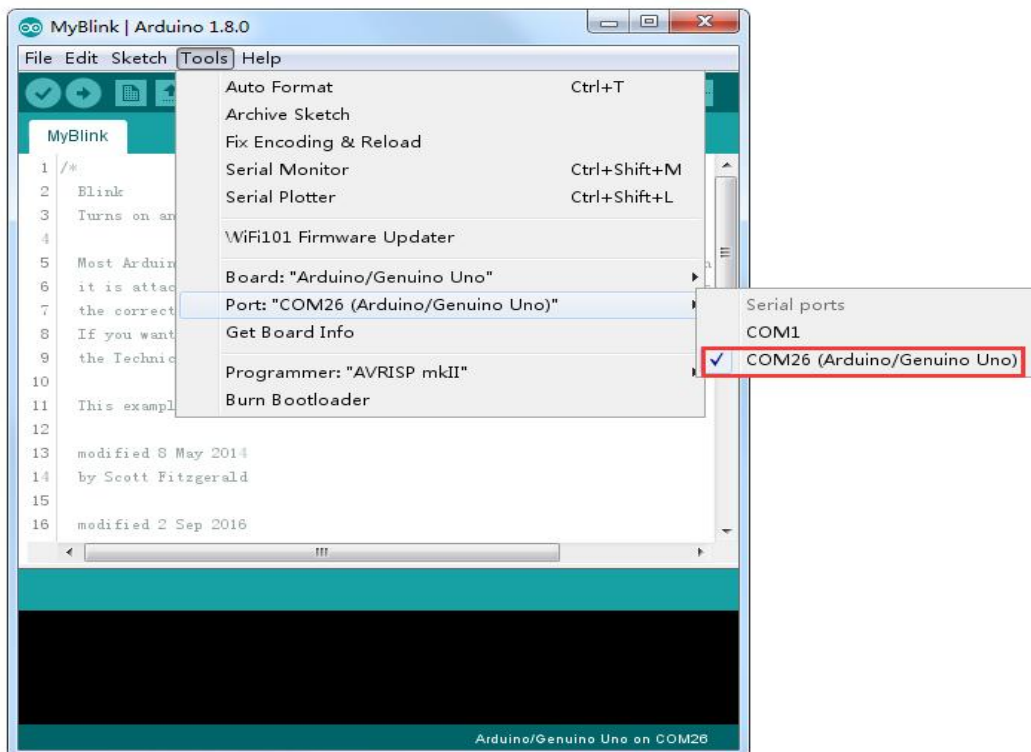

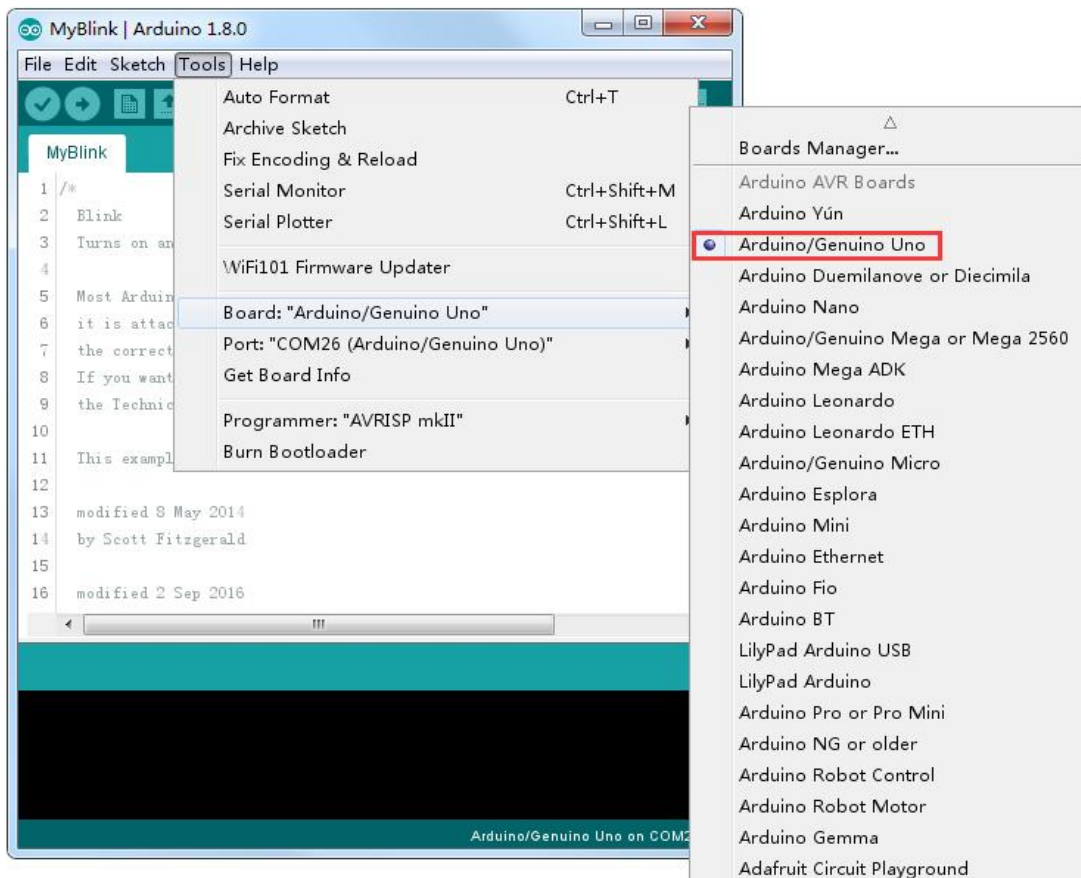

You have saved your copy of 'Blink' in your sketchbook. This means that if you ever want to find it again, you can just open it using the File > Sketchbook menu option.

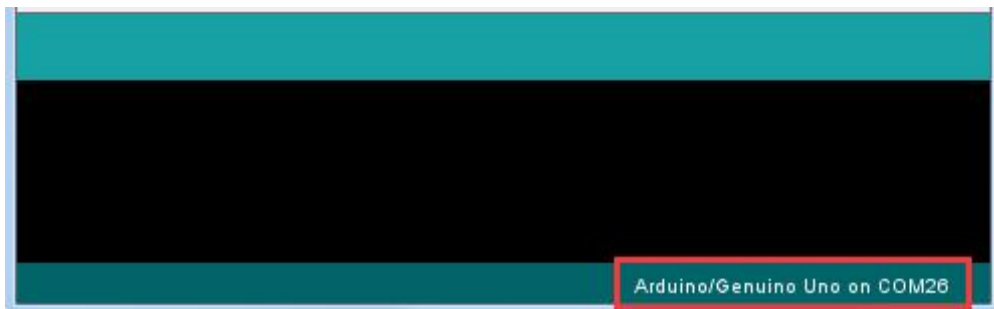

Attach your Arduino board to your computer with the USB cable and check that the 'Board Type' and 'Serial Port' are set correctly.

Note: The Board Type and Serial Port here are not necessarily the same as shown in picture. If you are using 2560, then you will have to choose Mega 2560 as the Board Type, other choices can be made in the same manner. And the Serial Port displayed for everyone is different, despite COM 26 chosen here, it could be COM3 or COM4 on your computer. A right COM port is supposed to be COMX (arduino XXX), which is by the certification criteria.

The Arduino IDE will show you the current settings for board at the bottom of the window.

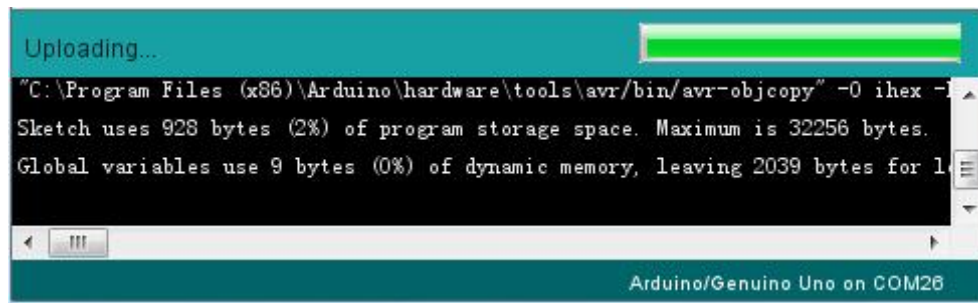

Click on the 'Upload' button. The second button from the left on the toolbar.

If you watch the status area of the IDE, you will see a progress bar and a series of messages. At first, it will say 'Compiling Sketch...'. This converts the sketch into a format suitable for uploading to the board.

Next, the status will change to 'Uploading'. At this point, the LEDs on the Arduino should start to flicker as the sketch is transferred.

Finally, the status will change to 'Done'.

The other message tells us that the sketch is using 928 bytes of the 32,256 bytes available. After the 'Compiling Sketch..' stage you could get the following error message:

It can mean that your board is not connected at all, or the drivers have not been installed (if necessary) or that the wrong serial port is selected.

If you encounter this, go back to Lesson 0 and check your installation.

Once the upload has completed, the board should restart and start blinking. Open the code

Note that a huge part of this sketch is composed of comments. These are not actual program instructions; rather, they just explain how the program works. They are there for your benefit.

Everything between `/*` and `*/` at the top of the sketch is a block comment; it explains what the sketch is for.

Single line comments start with `//` and everything up until the end of that line is considered a comment.

The first line of code is: `int led = 13;`

As the comment above it explains, this is giving a name to the pin that the LED is attached to. This is 13 on most Arduinos, including the UNO and Leonardo.

Next, we have the 'setup' function. Again, as the comment says, this is executed when the reset button is pressed. It is also executed whenever the board resets for any reason, such as power first being applied to it, or after a sketch has been uploaded.

```
void setup() {  
  // initialize the digital pin as an output. pinMode(led, OUTPUT);  
}
```

Every Arduino sketch must have a 'setup' function, and the place where you might want to add instructions of your own is between the `{` and the `}`.

In this case, there is just one command there, which, as the comment states tells the Arduino board that we are going to use the LED pin as an output.

It is also mandatory for a sketch to have a 'loop' function. Unlike the 'setup' function that only runs once, after a reset, the 'loop' function will, after it has finished running its commands, immediately start again.

```
void loop() {  
  digitalWrite(led, HIGH);      // turn the LED on (HIGH is the voltage level)  
  delay(1000);                  // wait for a second  
  digitalWrite(led, LOW);       // turn the LED off by making the voltage LOW  
  delay(1000);                  // wait for a second  
}
```

Inside the loop function, the commands first of all turn the LED pin on (HIGH), then 'delay' for 1000 milliseconds (1 second), then turn the LED pin off and pause for another second.

You are now going to make your LED blink faster. As you might have guessed, the key to this lies in changing the parameter in `()` for the 'delay' command.

```
30 // the loop function runs over and over again forever
31 void loop() {
32   digitalWrite(LED_BUILTIN, HIGH); // turn the LED on (HIGH is the volt
33   delay(500)                        // wait for a second
34   digitalWrite(LED_BUILTIN, LOW);  // turn the LED off by making the vo
35   delay(500)                        // wait for a second
36 }
```

This delay period is in milliseconds, so if you want the LED to blink twice as fast, change the value from 1000 to 500. This would then pause for half a second each delay rather than a whole second.

Upload the sketch again and you should see the LED start to blink more quickly.

Lesson 3 LED

Overview

In this lesson, you will learn how to change the brightness of an LED by using different values of resistor.

Component Required:

- (1) x KUONGSHUN UNO R3
- (1) x 5mm red LED
- (1) x 220 ohm resistor
- (1) x 1k ohm resistor
- (1) x 10k ohm resistor
- (2) x M-M wires (Male to Male jumper wires)

Component Introduction

BREADBOARD MB-102:

A breadboard enables you to prototype circuits quickly, without having to solder the connections. Below is an example.

Breadboards come in various sizes and configurations. The simplest kind is just a grid of holes in a plastic block. Inside are strips of metal that provide electrical connection between holes in the shorter rows. Pushing the legs of two different components into the same row joins them together electrically. A deep channel running down the middle indicates that there is a break in connections there, meaning, you can push a chip in with the legs at either side of the channel without connecting them together. Some breadboards have two strips of holes running along the long edges of the board that are separated from the main grid. These have strips running down the length of the board inside and provide a way to connect a common voltage. They are usually in pairs for +5 volts and ground. These strips are referred to as rails and they enable you to connect power to many components or points in the board.

While breadboards are great for prototyping, they have some limitations. Because the connections are push-fit and temporary, they are not as reliable as soldered connections. If you are having intermittent problems with a circuit, it could be due to a poor connection on a breadboard.

LED:

LEDs make great indicator lights. They use very little electricity and they pretty much last forever.

In this lesson, you will use perhaps the most common of all LEDs: a 5mm red LED. 5mm refers to the diameter of the LED. Other common sizes are 3mm and 10mm. You cannot directly connect an LED to a battery or voltage source because 1) the LED has a positive and a negative lead and will not light if placed the wrong way and 2) an LED must be used with a resistor to limit or 'choke' the amount of current flowing through it; otherwise, it will burn out!

If you do not use a resistor with an LED, then it may well be destroyed almost immediately, as too much current will flow through, heating it and destroying the 'junction' where the light is produced.

There are two ways to tell which is the positive lead of the LED and which the negative.

Firstly, the positive lead is longer.

Secondly, where the negative lead enters the body of the LED, there is a flat edge to the case of the LED.

If you happen to have an LED that has a flat side next to the longer lead, you should assume that the longer lead is positive.

RESISTORS:

As the name suggests, resistors resist the flow of electricity. The higher the value of the resistor, the more it resists and the less electrical current will flow through it. We are going to use this to control how much electricity flows through the LED and therefore, how brightly it shines.

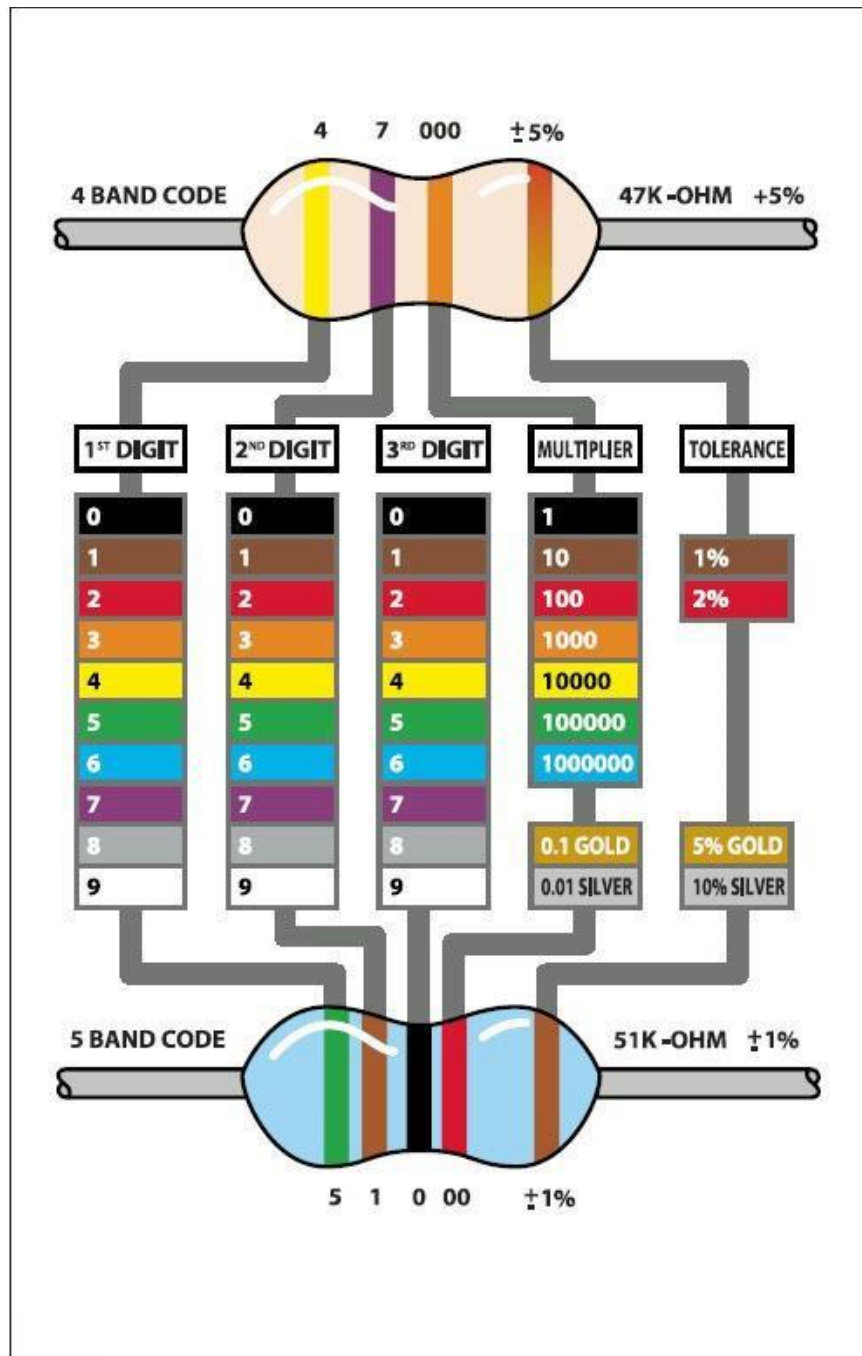

But first, more about resistors...

The unit of resistance is called the Ohm, which is usually shortened to Ω the Greek letter Omega. Because an Ohm is a low value of resistance (it doesn't resist much at all), we also denote the values of resistors in $k\Omega$ (1,000 Ω) and $M\Omega$ (1,000,000 Ω). These are called kilo-ohms and mega-ohms.

In this lesson, we are going to use three different values of resistor: 220 Ω , 1k Ω and 10k Ω . These resistors all look the same, except that they have different colored stripes on them. These stripes tell you the value of the resistor.

The resistor color code has three colored stripes and then a gold stripe at one end.

Unlike LEDs, resistors do not have a positive and negative lead. They can be connected either way around.

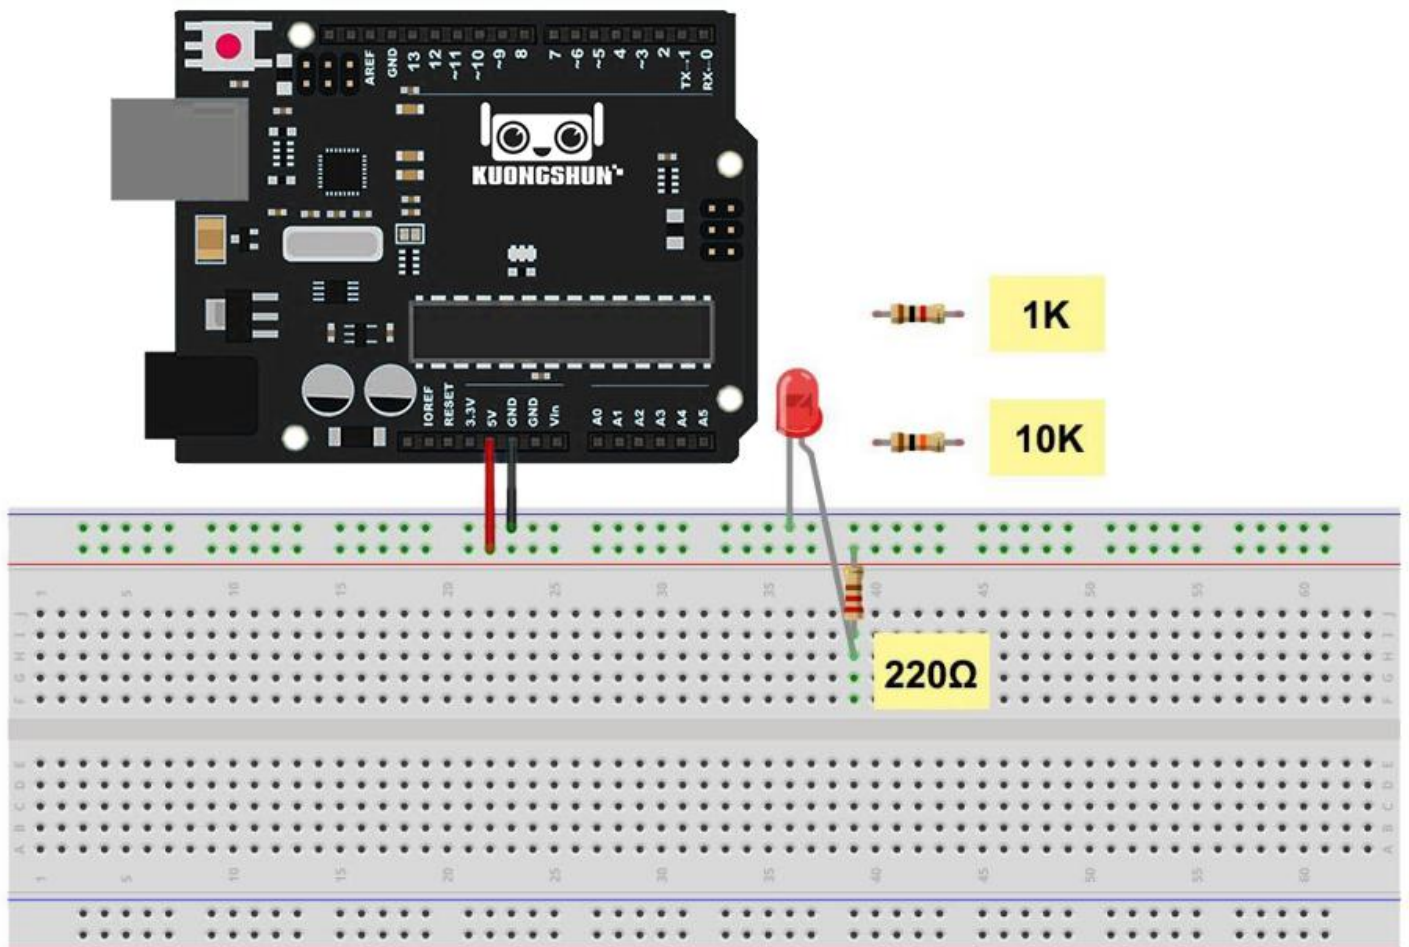

If you find this approach method too complicated, you can read the color ring flag on our resistors directly to determine its resistance value. Or you may use a digital multimeter instead.

Connection

Schematic

Wiring diagram

The UNO is a convenient source of 5 volts, which we will use to provide power to the LED and the resistor. You do not need to do anything with your UNO, except to plug it into a USB cable.

With the 220 Ω resistor in place, the LED should be quite bright. If you swap out the 220 Ω resistor for the 1k Ω resistor, then the LED will appear a little dimmer. Finally, with the 10 k Ω resistor in place, the LED will be just about visible. Pull the red jumper lead out of the breadboard and touch it into the hole and remove it, so that it acts like a switch. You should just be able to notice the difference.

At the moment, you have 5V going to one leg of the resistor, the other leg of the resistor going to the positive side of the LED and the other side of the LED going to GND. However, if we moved the resistor so that it came after the LED, as shown below, the LED will still light.

You will probably want to put the 220 Ω resistor back in place.

It does not matter which side of the LED we put the resistor, as long as it is there somewhere

Example picture

Lesson 4 Digital Inputs

Overview

In this lesson, you will learn to use push buttons with digital inputs to turn an LED on and off.

Pressing the button will turn the LED on; pressing the other button will turn the LED off.

Component Required:

- (1) x KUONGSHUN UNO R3
- (1) x 830 Tie-points Breadboard
- (1) x 5mm red LED
- (1) x 220 ohm resistor
- (1) x push switches
- (7) x M-M wires (Male to Male jumper wires)

Component Introduction

PUSH SWITCHES:

Switches are really simple components. When you press a button or flip a lever, they connect two contacts together so that electricity can flow through them.

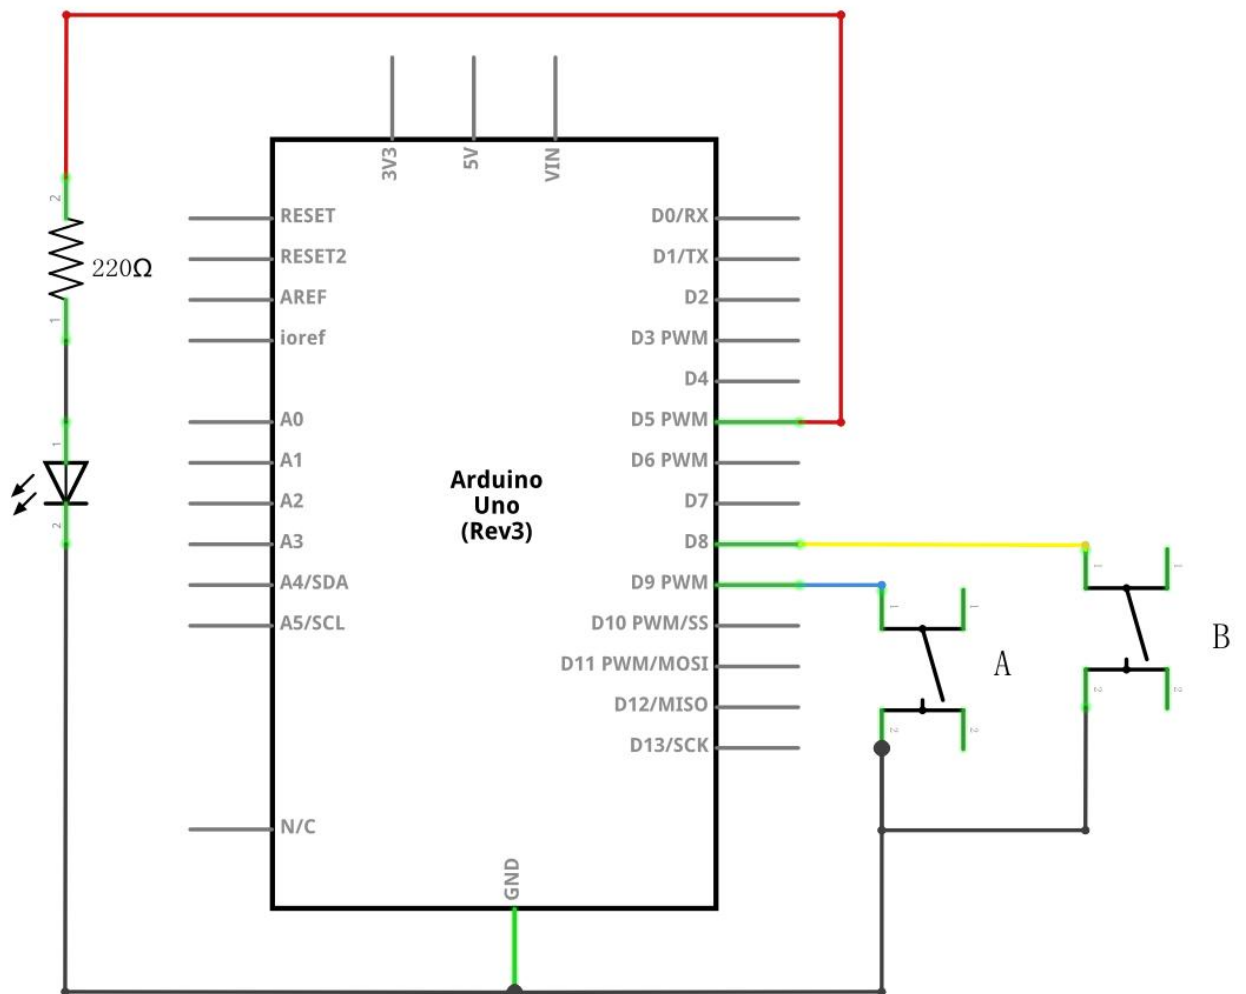

The little tactile switches that are used in this lesson have four connections, which can be a little confusing.

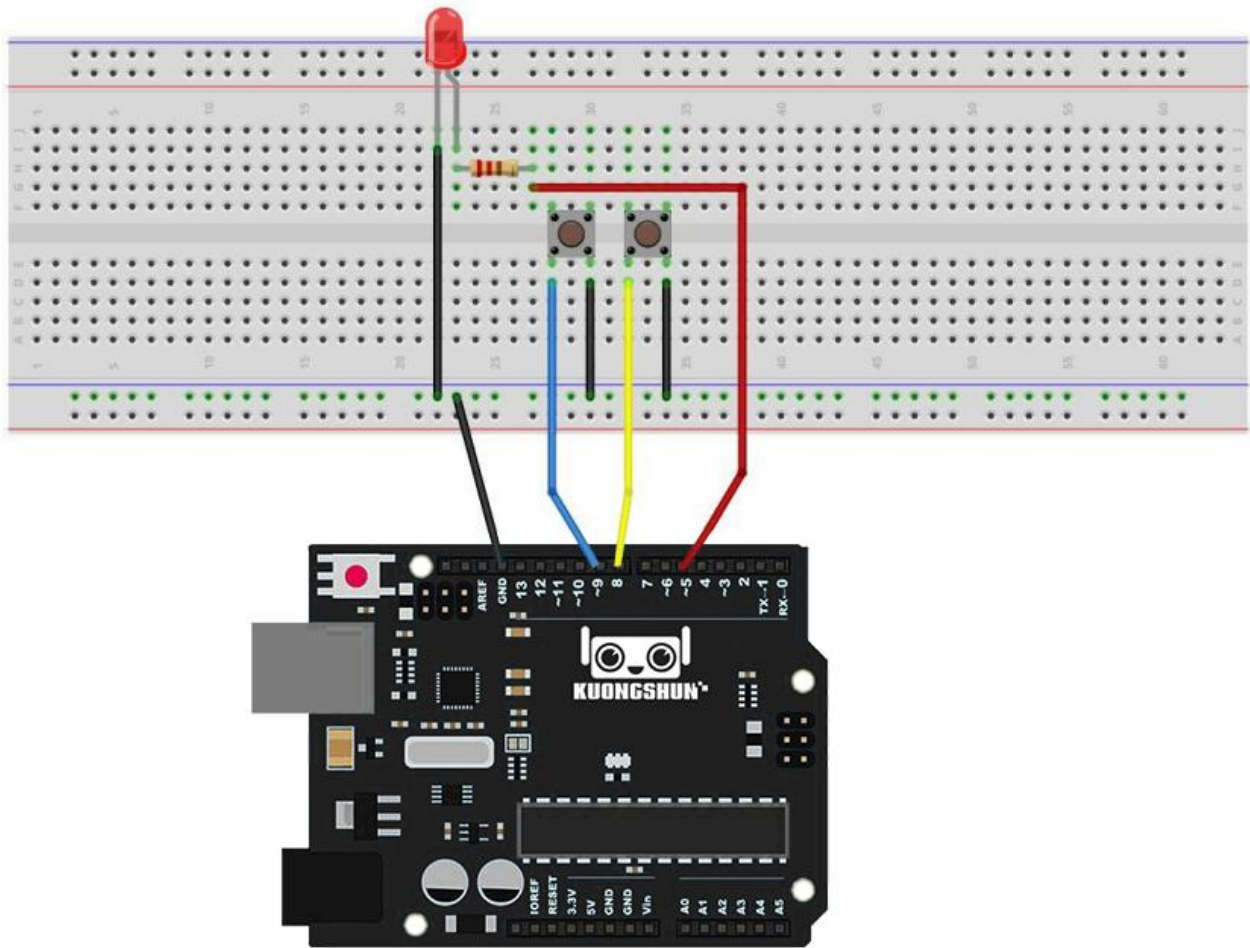

Actually, there are only really two electrical connections. Inside the switch package, pins B and C are connected together, as are A and D.

Connection

Schematic

Wiring diagram

Although the bodies of the switches are square, the pins protrude from opposite sides of the switch. This means that the pins will only be far enough apart when they are placed correctly on the breadboard.

Remember that the LED has to have the shorter negative lead to the left.

Code

After wiring, please open program in the code folder- Lesson 5 Digital Inputs, and press **UPLOAD** to upload the program. If errors are prompted, see Lesson 2 for details about the tutorial on program upload.

Load the sketch onto your UNO board. Pressing the left button will turn the LED on while pressing the right button will turn it off.

The first part of the sketch defines three variables for the three pins that are to be used. The 'ledPin' is the output pin and 'button A pin' will refer to the switch nearer the top of the breadboard and 'button B pin' to the other switch.

The 'setup' function defines the ledPin as being an OUTPUT as normal, but now we have the two inputs to deal with. In this case, we use the set the pinMode to be 'INPUT_PULLUP' like this:

```
pinMode(buttonApin, INPUT_PULLUP); pinMode(buttonBpin, INPUT_PULLUP);
```

The pin mode of INPUT_PULLUP means that the pin is to be used as an input, but that if nothing else is connected to the input, it should be 'pulled up' to HIGH. In other words, the default value for the input is HIGH, unless it is pulled LOW by the action of pressing the button.

This is why the switches are connected to GND. When a switch is pressed, it connects the input pin to GND, so that it is no longer HIGH.

Since the input is normally HIGH and only goes LOW when the button is pressed, the logic is a little upside down. We will handle this in the 'loop' function.

```
void loop()
{
  if (digitalRead(buttonApin) == LOW)
  {
    digitalWrite(ledPin, HIGH);
  }
  if (digitalRead(buttonBpin) == LOW)
```

{

```
digitalWrite(ledPin, LOW);  
}  
}
```

In the 'loop' function there are two 'if' statements. One for each button. Each does an 'digitalRead' on the appropriate input.

Remember that if the button is pressed, the corresponding input will be LOW, if button A is low, then a 'digitalWrite' on the led Pin turns it on.

Similarly, if button B is pressed, a LOW is written to the led Pin.

Example picture

Lesson 5 Active buzzer

Overview

In this lesson, you will learn how to generate a sound with an active buzzer.

Component Required:

- (1) x KUONGSHUN UNO R3
- (1) x Active buzzer
- (2) x F-M wires (Female to Male DuPont wires)

Component Introduction

BUZZER:

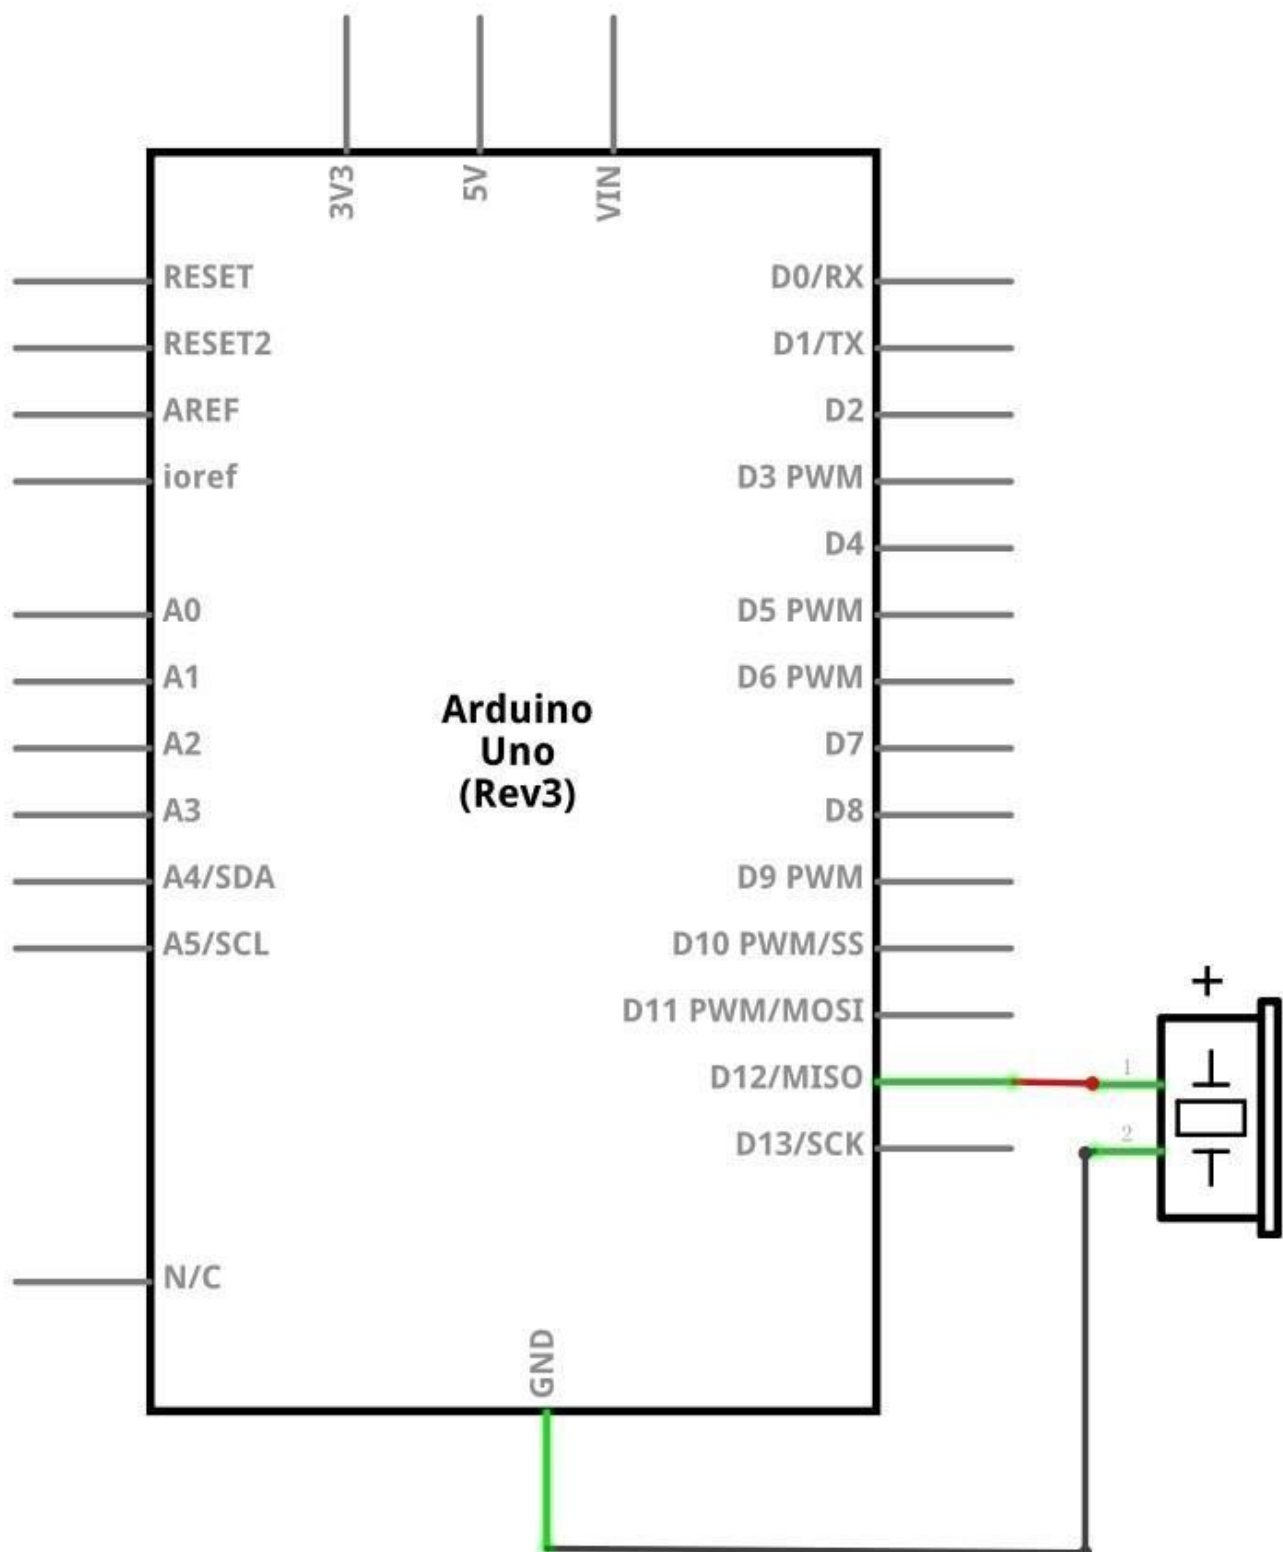

Electronic buzzers are DC-powered and equipped with an integrated circuit. They are widely used in computers, printers, photocopiers, alarms, electronic toys, automotive electronic devices, telephones, timers and other electronic products for voice devices. Buzzers can be categorized as active and passive ones. Turn the pins of two buzzers face up. The one with a green circuit board is a passive buzzer, while the other enclosed with a black tape is an active one.

The difference between the two is that an active buzzer has a built-in oscillating source, so it will generate a sound when electrified. A passive buzzer does not have such a source so it will not tweet if DC signals are used; instead, you need to use square waves whose frequency is between 2K and 5K to drive it. The active buzzer is often more expensive than the passive one because of multiple built-in oscillating circuits.

Connection

Schematic

Wiring diagram

Code

After wiring, please open the program in the code folder- Lesson 6 Making Sounds and click UPLOAD to upload the program. See Lesson 2 for details about program uploading if there are any errors.

Example picture

Lesson 6 Passive Buzzer

Overview

In this lesson, you will learn how to use a passive buzzer.

The purpose of the experiment is to generate eight different sounds, each sound lasting 0.5 seconds: from Alto Do (523Hz), Re (587Hz), Mi (659Hz), Fa (698Hz), So (784Hz), La (880Hz), Si (988Hz) to Treble Do (1047Hz).

Component Required:

- (1) x KUONGSHUN UNO R3
- (1) x Passive buzzer
- (2) x F-M wires (Female to Male DuPont wires)

Component Introduction

Passive Buzzer:

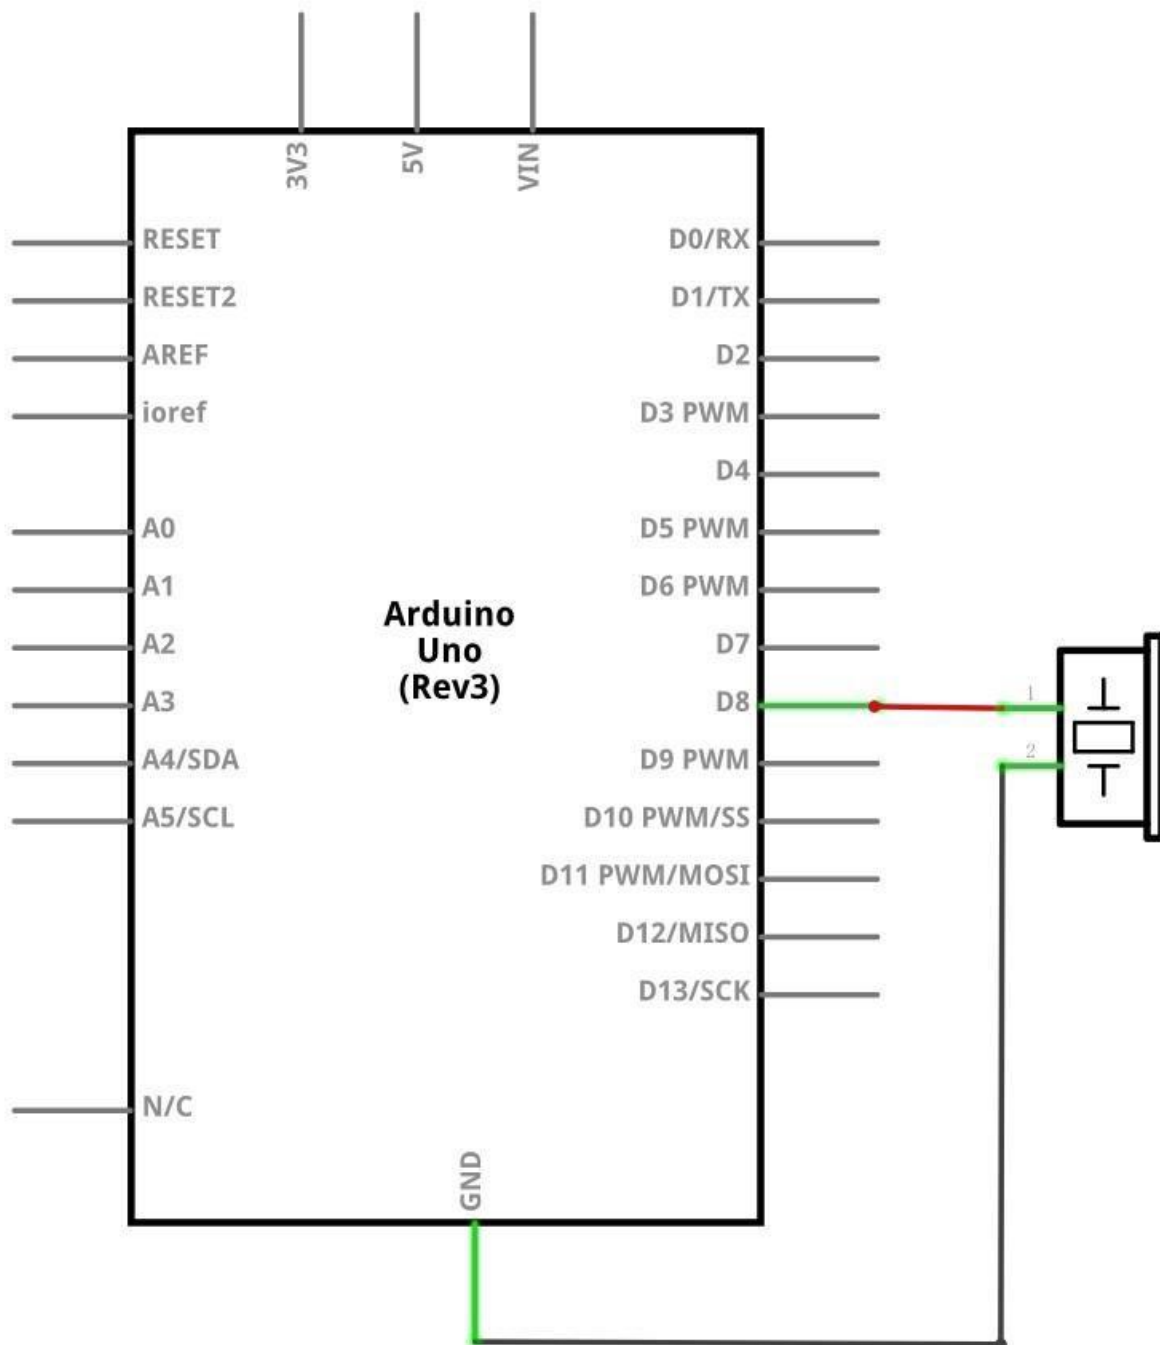

The working principle of passive buzzer is using PWM generating audio to make the air to vibrate. Appropriately changed as long as the vibration frequency, it can generate different sounds. For example, sending a pulse of 523Hz, it can generate Alto Do, pulse of 587Hz, it can generate midrange Re, pulse of 659Hz, it can produce midrange Mi. By the buzzer, you can play a song.

We should be careful not to use the UNO R3 board analog Write () function to generate a pulse to the buzzer, because the pulse output of analog Write () is fixed (500Hz).

Connection

Schematic

Wiring diagram

Wiring the buzzer connected to the UNO R3 board, the red (positive) to the pin8, black wire (negative) to the GND.

Code

After wiring, please open the program in the code folder- Lesson 7 Passive Buzzer and click UPLOAD to upload the program. See Lesson 2 for details about program uploading if there are any errors.

Before you can run this, make sure that you have installed the <itches> library or re-install it, if necessary. Otherwise, your code won't work.

For details about loading the library file, see Lesson1.

Example picture

Lesson 7 Tilt Ball Switch

Overview

In this lesson, you will learn how to use a tilt ball switch in order to detect small angle of inclination.

Component Required: |

- (1) x KUONGSHUN UNO R3
- (1) x Tilt Ball switch
- (2) x F-M wires (Female to Male DuPont wires)

Component Introduction

Tilt sensor:

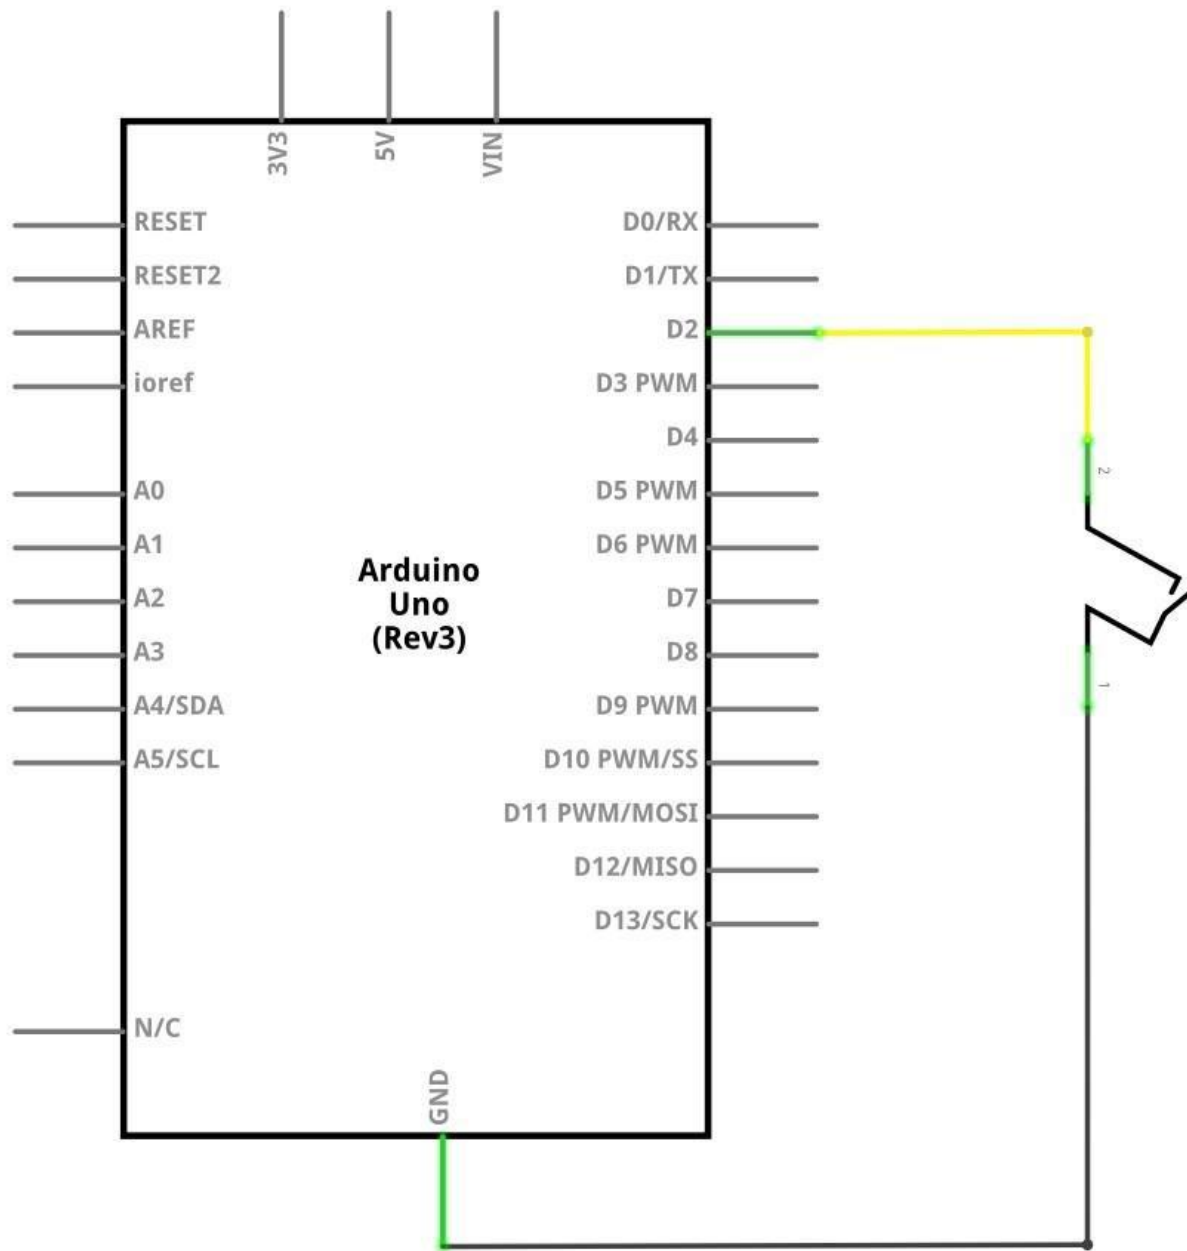

Tilt sensors (tilt ball switch) allow you to detect orientation or inclination. They are small, inexpensive, low-power and easy-to-use. If used properly, they will not wear out. Their simplicity makes them popular for toys, gadgets and appliances. Sometimes, they are referred to as "mercury switches", "tilt switches" or "rolling ball sensors" for obvious reasons.

They are usually made up of a cavity of some sort (cylindrical is popular, although not always) with a conductive free mass inside, such as a blob of mercury or rolling ball. One end of the cavity has two conductive elements (poles). When the sensor is oriented so that that end is downwards, the mass rolls onto the poles and shorts them, acting as a switch throw.

While not as precise or flexible as a full accelerometer, tilt switches can detect motion or orientation. Another benefit is that the big ones can switch power on their own. Accelerometers, on the other hand, output digital or analog voltage that must then be analyzed using extra circuitry.

Connection

Schematic

Wiring diagram

Code

After wiring, please open the program in the code folder- Lesson 8 Ball Switch and click **UPLOAD** to upload the program. See Lesson 2 for details about program uploading if there are any errors.

Example picture

Lesson 8 Servo

Overview

Servo is a type of geared motor that can only rotate 180 degrees. It is controlled by sending electrical pulses from your UNO R3 board. These pulses tell the servo what position it should move to. The Servo has three wires, of which the brown one is the ground wire and should be connected to the GND port of UNO, the red one is the power wire and should be connected to the 5v port, and the orange one is the signal wire and should be connected to the Dig #9 port.

Component Required:

- (1) x KUONGSHUN UNO R3
- (2) x Servo (SG90)
- (3) x M-M wires (Male to Male jumper wires)

Component Introduction

SG90

- Universal for JR and FP connector
- Cable length : 25cm
- No load; Operating speed: 0.12 sec / 60 degree (4.8V), 0.10 sec / 60 degree (6.0V)
- Stall torque (4.8V): 1.6kg/cm
- Temperature : -30~60'C
- Dead band width: 5us
- Working voltage: 3.5~6V
- Dimension : 1.26 in x 1.18 in x 0.47 in (3.2 cm x 3 cm x 1.2 cm)
- Weight : 4.73 oz (134 g)
-

Connection

Schematic

Wiring diagram

Code

After wiring, please open the program in the code folder- Lesson 9 Servo and click UPLOAD to upload the program. See Lesson 2 for details about program uploading if there are any errors.

Before you can run this, make sure that you have installed the < Servo> library or re-install it, if necessary. Otherwise, your code won't work.

For details about loading the library file, see Lesson1.

Example picture

In the picture, the brown wire of servo is adapted via the black M-M wires, the red one is adapted via the red M-M wires, and the orange one is adapted via the yellow M-M wires.

Lesson 9 RGB LED Module

Overview

In this experiment, we will learn how to use RGB LED module. RGB LED module is made from a patch of full-color LED. By adjusting the voltage input of R, G, B pins, we can adjust the strength of the three primary colors (red/blue/green) so as to implementation result of full color effect.

Component Required:

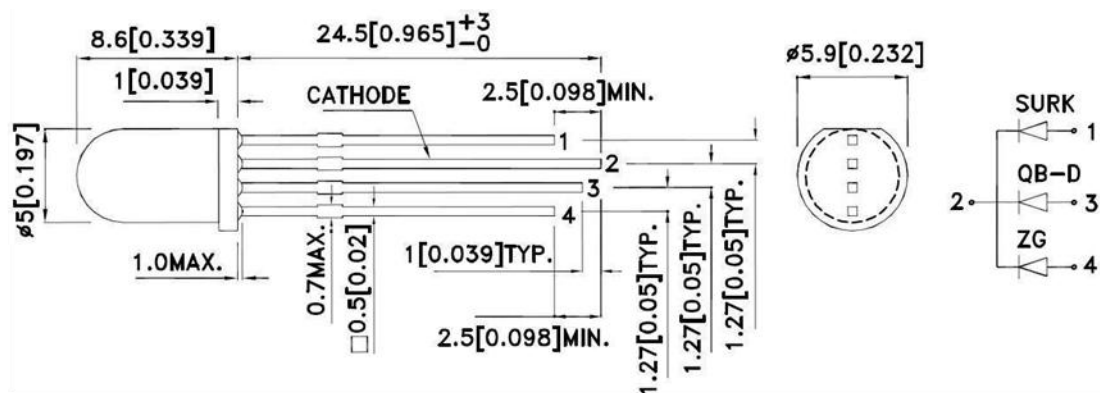

- (1) x KUONGSHUN UNO R3
- (1) x RGB LED Module
- (4) x F-M wires (Female to Male DuPont wires)

Component Introduction

RGB LED Module

RGB-LED with clear lens and built-in 150 ohm series resistor for 5 V operation.

Electrical / Optical Characteristics at TA=25°C

Symbol	Parameter	Device	Typ.	Max.	Units	Test Conditions

Lesson 10 Membrane Switch Module

Overview

In this project, we will go over how to integrate a keyboard with an UNO R3 board so that the UNO R3 can read the keys being pressed by a user.

Keypads are used in all types of devices, including cell phones, fax machines, microwaves, ovens, door lock, etc. They're practically everywhere. Tons of electronic devices use them for user input.

So knowing how to connect a keypad to a micro controller such as an UNO R3 board is very valuable for building many different types of commercial products.

At the end when all is connected properly and programmed, when a key is pressed, it shows up at the Serial Monitor on your computer. Whenever you press a key, it shows up on the Serial Monitor. For simplicity purposes, we start at simply showing the key pressed on the computer.

For this project, the type of keypad we will use is a matrix keypad. This is a keypad that follows an encoding scheme that allows it to have much less output pins than there are keys. For example, the matrix keypad we are using has 16 keys (0-9, A-D,

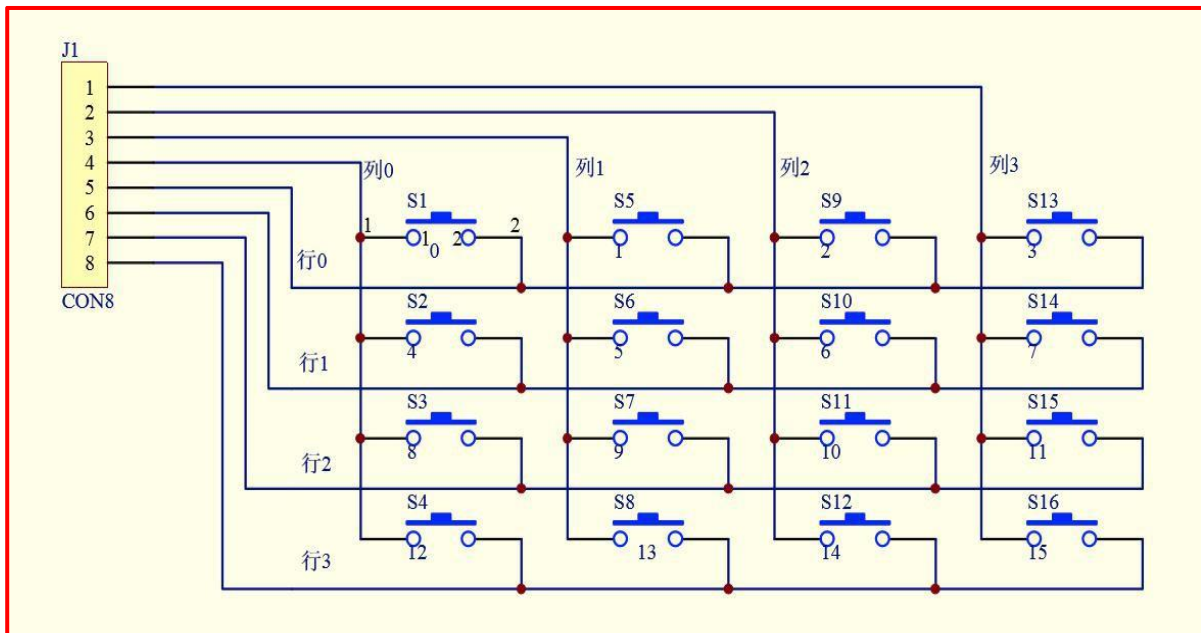

*, #), yet only 8 output pins. With a linear keypad, there would have to be 17 output pins (one for each key and a ground pin) in order to work. The matrix encoding scheme allows for less output pins and thus much less connections that have to make for the keypad to work. In this way, they are more efficient than linear keypads, being that they have less wiring.

Component Required:

- (1) x KUONGSHUN UNO R3
- (1) x Membrane switch module
- (8) x M-M wires (Male to Male jumper wires)

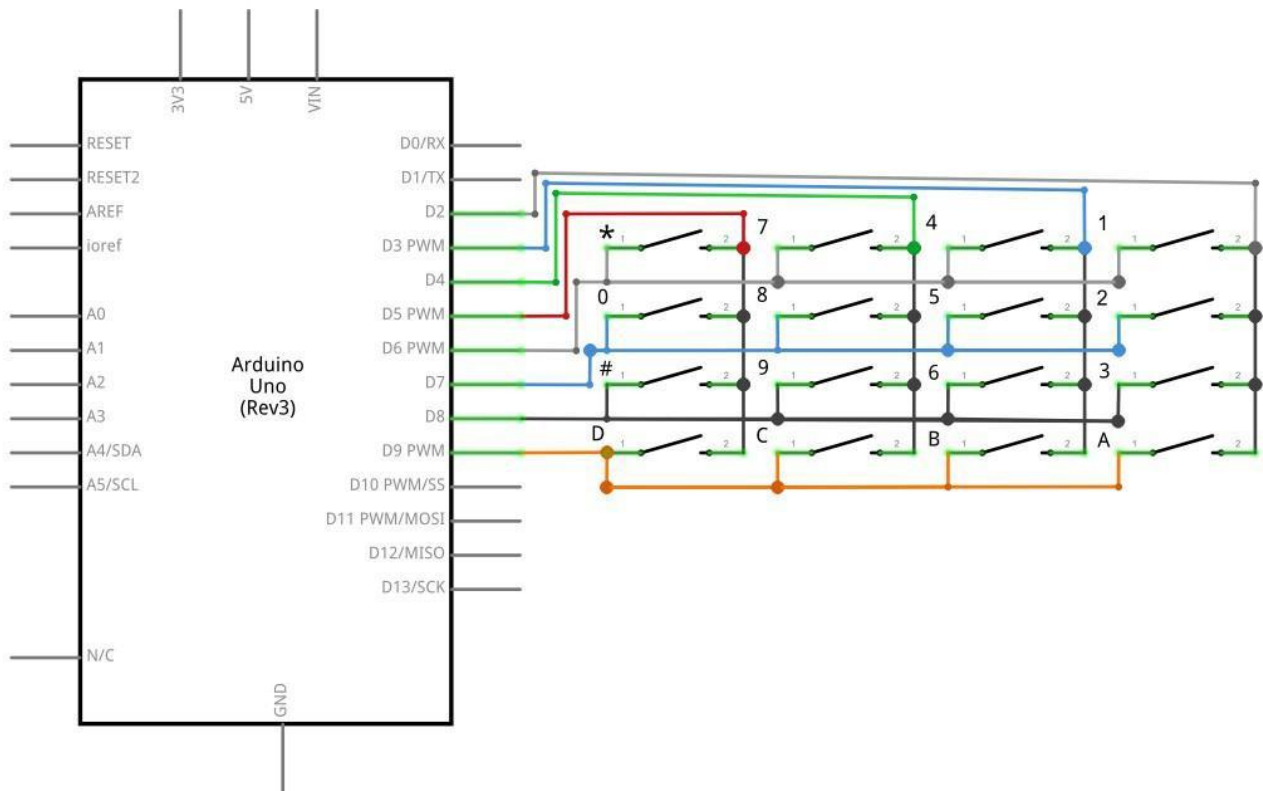

Module Schematic

Module PCB

Connection Schematic

Wiring diagram

When connecting the pins to the UNO R3 board, we connect them to the digital output pins, D9-D2. We connect the first pin of the keypad to D9, the second pin to D8, the third pin to D7, the fourth pin to D6, the fifth pin to D5, the sixth pin to D4, the seventh pin to D3, and the eighth pin to D2.

These are the connections in a table:

Keypad Pin	Connects to Arduino Pin...
1	D9
2	D8
3	D7
4	D6
5	D5
6	D4
7	D3
8	D2

Code

After wiring, please open the program in the code folder- Lesson 11 Membrane Switch Module and click UPLOAD to upload the program. See Lesson 2 for details about program uploading if there are any errors.

Before you can run this, make sure that you have installed the < Keypad > library or re-install it, if necessary. Otherwise, your code won't work.

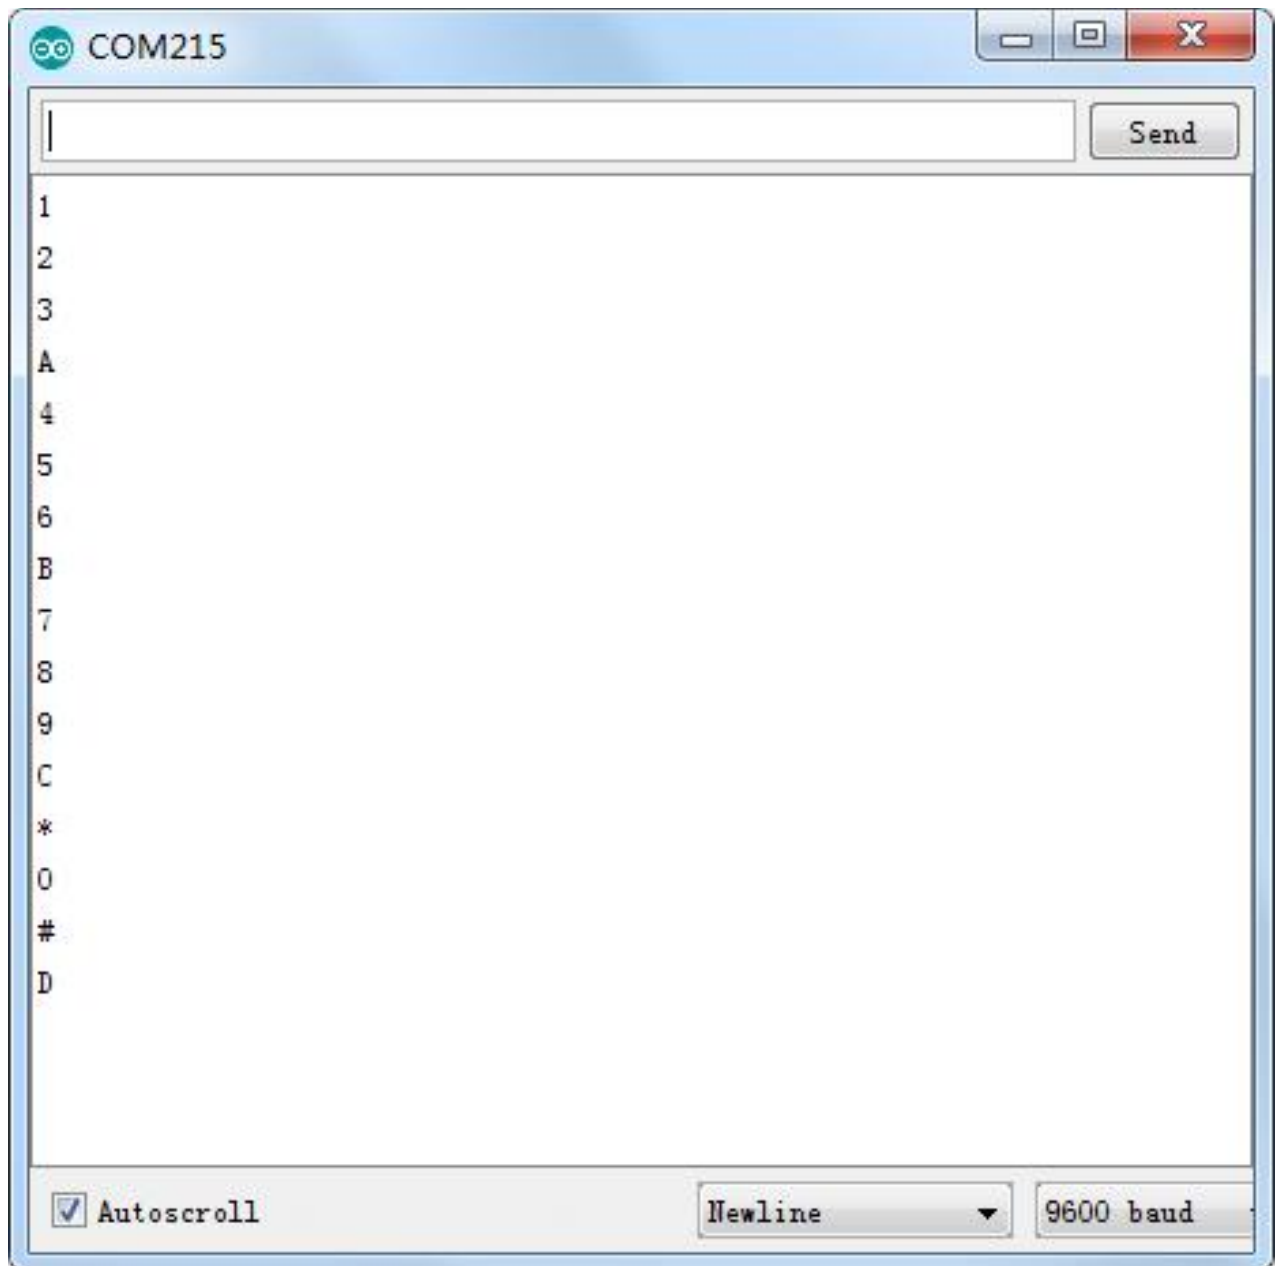

For details about loading the library file, see Lesson1.

Example picture

With this code, once we press a key on the keypad, it should show up on the serial monitor of the Arduino software once the code is compiled and uploaded to the UNO R3 board.

[Click the Serial Monitor button to turn on the serial monitor.](#) The basics about the serial monitor are introduced in details in [Lesson1](#).

Lesson 11 DHT11 Temperature and Humidity Sensor

Overview

In this tutorial we will learn how to use a DHT11 Temperature and Humidity Sensor. It's accurate enough for most projects that need to keep track of humidity and temperature readings.

Again we will be using a Library specifically designed for these sensors that will make our code short and easy to write.

Component Required:

- (1) x KUONGSHUN UNO R3
- (1) x DHT11 Temperature and Humidity module
- (3) x F-M wires (Female to Male DuPont wires)

Component Introduction

Temp and humidity sensor:

DHT11 pins	
1	VCC
2	DATA
3	NC
4	GND

DHT11 digital temperature and humidity sensor is a composite Sensor which contains a calibrated digital signal output of the temperature and humidity. The dedicated digital modules collection technology and the temperature and humidity sensing technology are applied to ensure that the product has high reliability and

excellent long-term stability. The sensor includes a resistive sense of wet components and a NTC temperature measurement devices, and connects with a high-performance 8-bit micro controller.

Applications: HVAC, dehumidifier, testing and inspection equipment, consumer goods, automotive, automatic control, data loggers, weather stations, home appliances, humidity regulator, medical and other humidity measurement and control.

Product parameters

Relative humidity: Resolution: 16Bit Repeatability: $\pm 1\%$ RH

Accuracy: At 25°C $\pm 5\%$ RH

Interchangeability: fully interchangeable Response time: 1 / e (63%) of 25°C 6s

1m / s air 6s Hysteresis: $< \pm 0.3\%$ RH

Long-term stability: $< \pm 0.5\%$ RH / yr in Temperature:

Resolution: 16Bit Repeatability: $\pm 0.2^{\circ}\text{C}$ Range: At 25°C $\pm 2^{\circ}\text{C}$

Response time: 1 / e (63%) 10S Electrical Characteristics Power supply: DC 3.5 ~ 5.5V

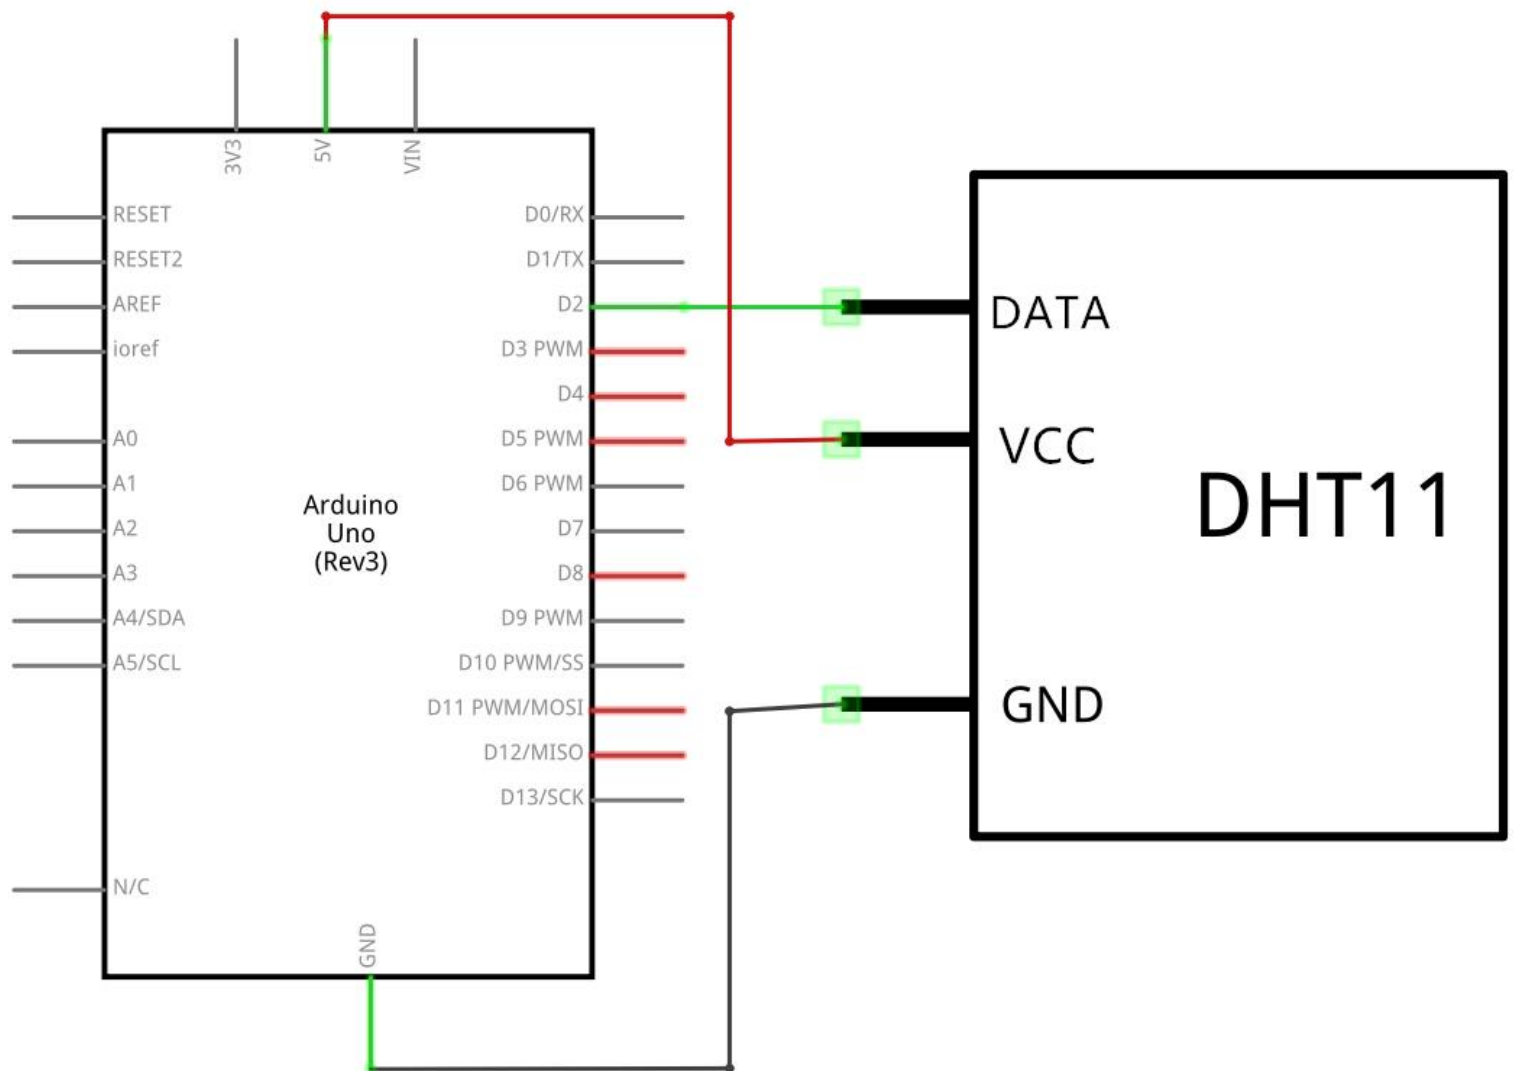

Supply Current: measurement 0.3mA standby 60 μA Sampling period: more than 2 seconds

Pin Description:

1. the VDD power supply 3.5 ~ 5.5V DC
2. DATA serial data, a single bus
3. NC, empty pin
4. GND ground, the negative power

Connection

Schematic

Wiring diagram

As you can see we only need 3 connections to the sensor, since one of the pin is not used. The connections are: Voltage, Ground and Signal which can be connected to any Pin on our UNO.

Code

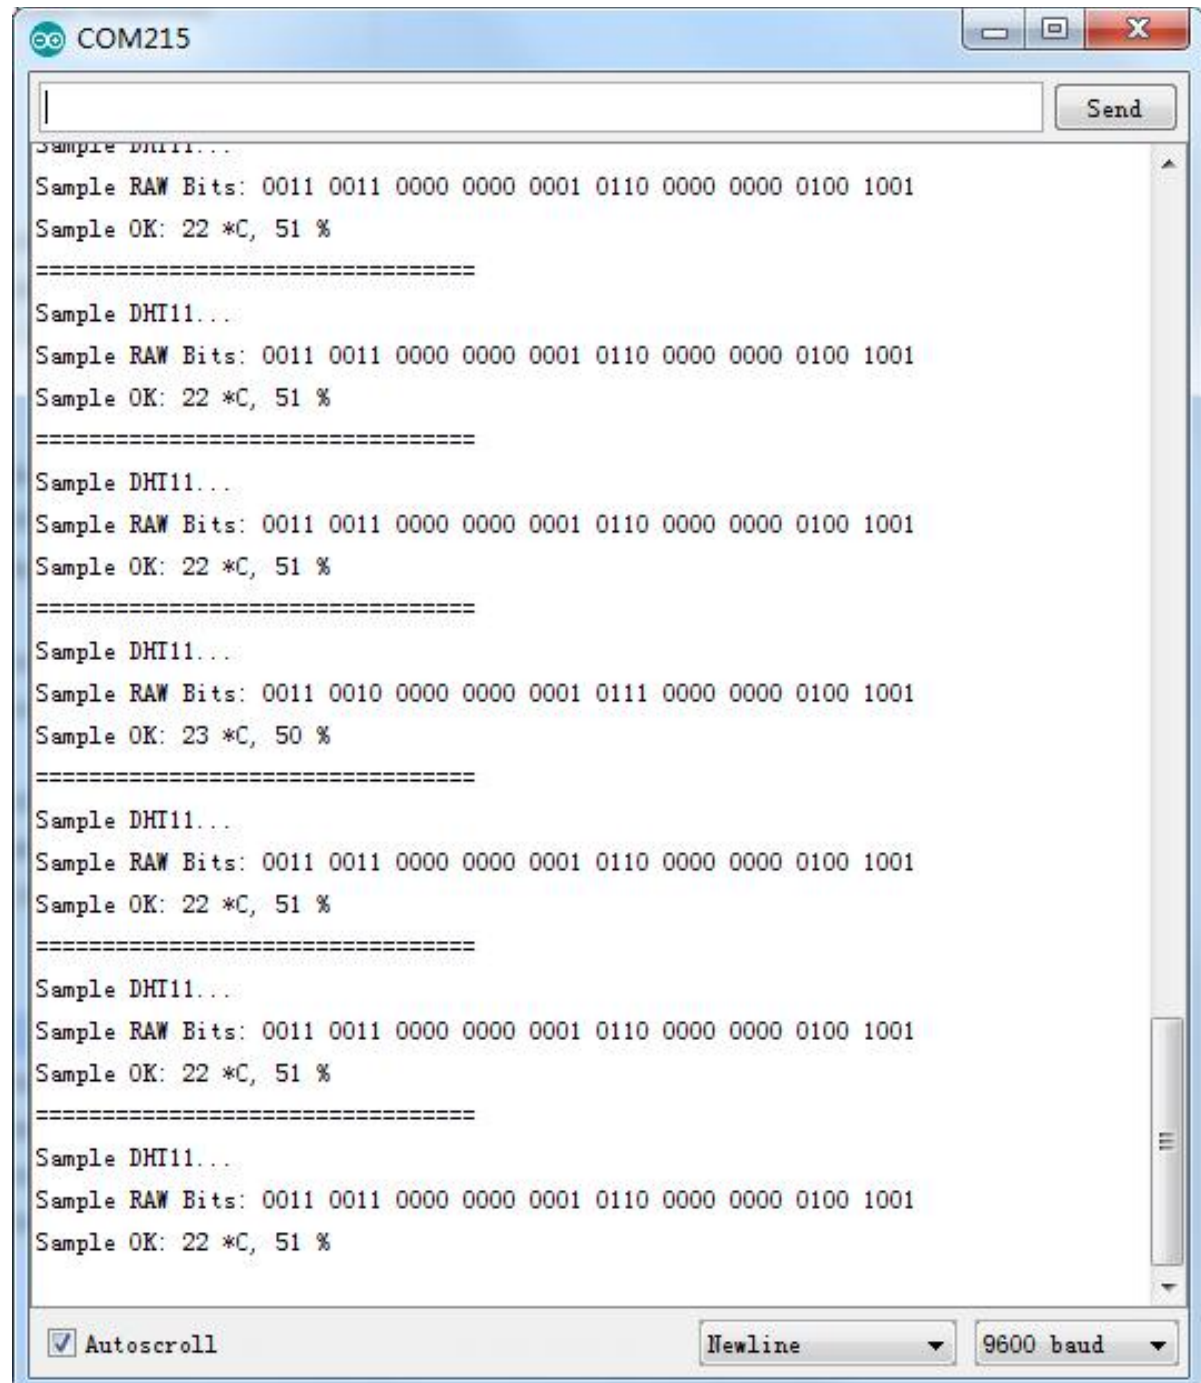

After wiring, please open the program in the code folder- Lesson 12 DHT11 Temperature and Humidity Sensor and click UPLOAD to upload the program. See Lesson 2 for details about program uploading if there are any errors.

Before you can run this, make sure that you have installed the < SimpleDHT> library or re-install it, if necessary. Otherwise, your code won't work. For details about the tutorial on the loading of library file, see Lesson 1

Upload the program then open the monitor, we can see the data as below: (It shows the temperature of the environment, we can see it is 22 degree)

[Click the Serial Monitor button to turn on the serial monitor.](#) The basics about the serial monitor are introduced in details in [Lesson 1](#).

Lesson 12 Analog Joystick Module

Overview

Analog joystick are a great way to add some control in your projects. In this tutorial we will learn how to use the analog joystick module.

Component Required:

- (1) x KUONGSHUN UNO R3
- (1) x Joystick module
- (5) x F-M wires (Female to Male DuPontwires)

Component Introduction

Joystick

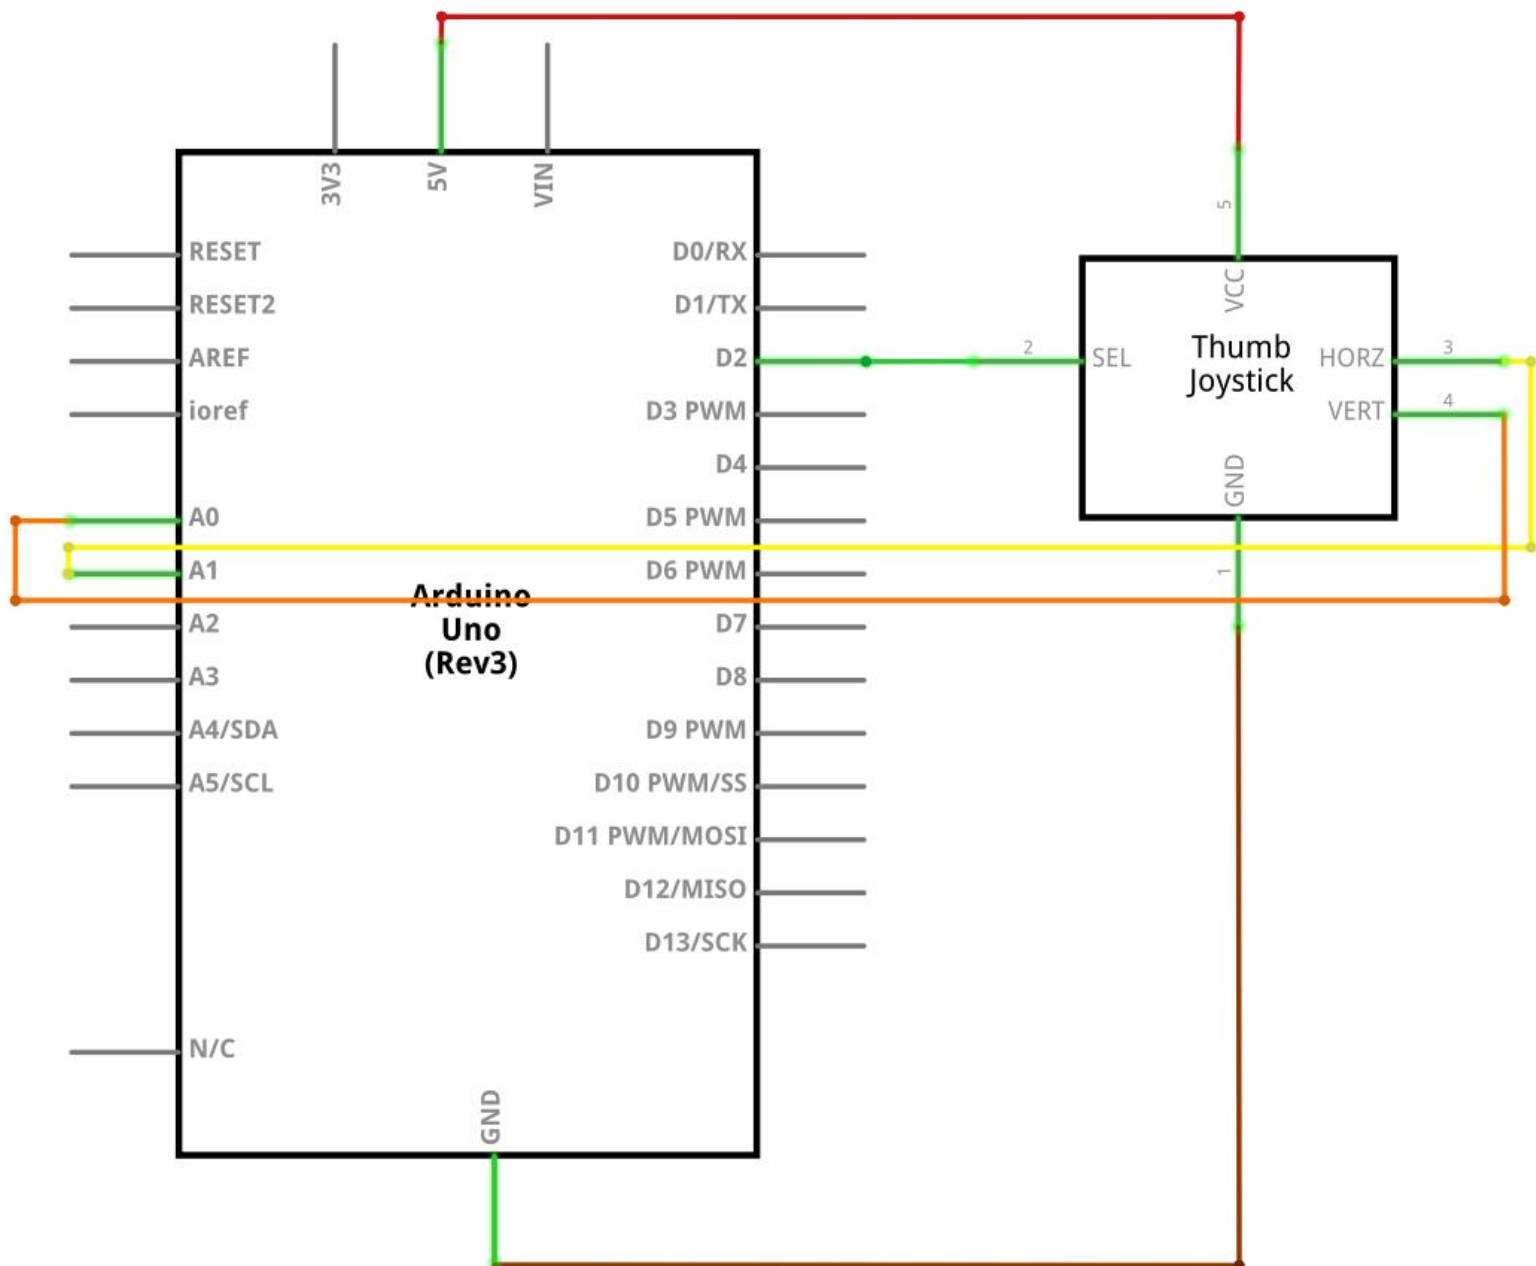

The module has 5 pins: VCC, Ground, X, Y, Key. Note that the labels on yours may be slightly different, depending on where you got the module from. The thumb stick is analog and should provide more accurate readings than simple 'directional' joystick tact use some forms of buttons, or mechanical switches. Additionally, you can press the joystick down (rather hard on mine) to activate a 'press to select' push- button.

We have to use analog Arduino pins to read the data from the X/Y pins, and a digital pin to read the button. The Key pin is connected to ground, when the joystick is pressed down, and is floating otherwise. To get stable readings from the Key /Select pin, it needs to be connected to VCC via a pull-up resistor. The built in resistors on the Arduino digital pins can be used. For a tutorial on how to activate the pull-up resistors for Arduino pins, configured as inputs

Connection

Schematic

Wiring diagram

We need 5 connections to the joystick.

The connections are: Key, Y, X, Voltage and Ground.

“Y and X” are Analog and “Key” is Digital. If you don’t need the switch then you can use only 4 pins.

Code

After wiring, please open the program in the code folder- Lesson 13 Analog Joystick Module and click **UPLOAD** to upload the program. See Lesson 2 for details about program uploading if there are any errors.

Analog joystick are basically potentiometers so they return analog values.

When the joystick is in the resting position or middle, it should return a value of about 512.

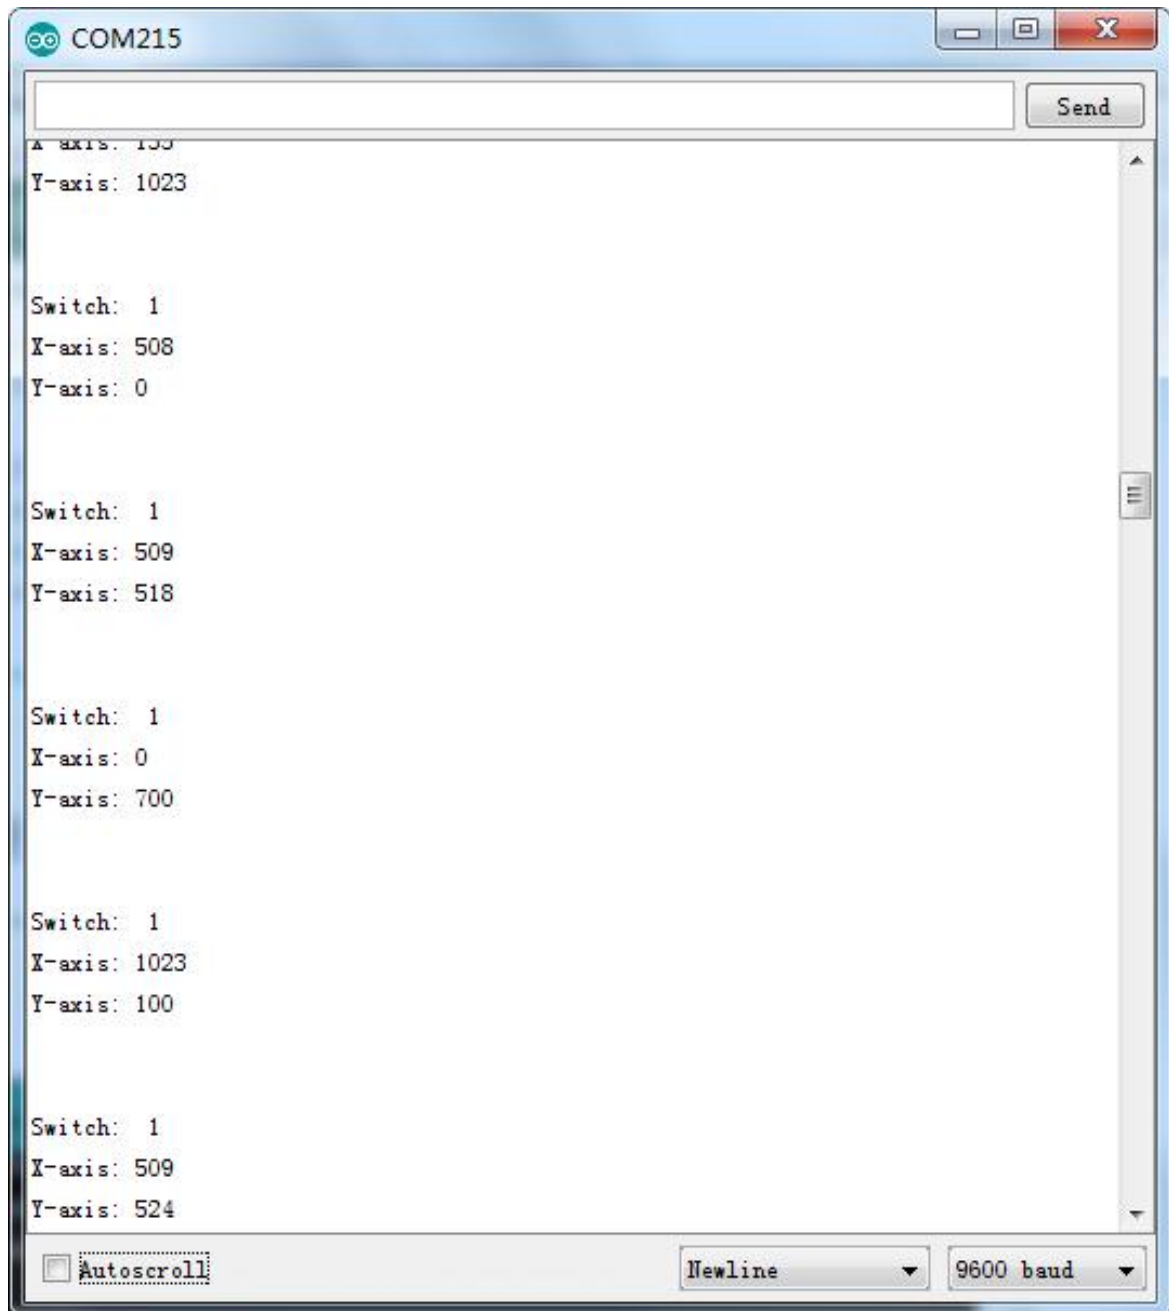

The range of values goes from 0 to 1024.

Example picture

Open the monitor then you can see the data asblow:

Click the Serial Monitor button to turn on the serial monitor. The basics about the serial monitor are introduced in details in Lesson1.

Lesson 13 IR Receiver

Overview

Using an IR Remote is a great way to have wireless control of your project.

Infrared remotes are simple and easy to use. In this tutorial we will be connecting the IR receiver to the UNO, and then use a Library that was designed for this particular sensor.

In our sketch we will have all the IR Hexadecimal codes that are available on this remote, we will also detect if the code was recognized and also if we are holding down a key.

Component Required:

- (1) x KUONGSHUN UNO R3
- (1) x IR receiver
- (1) x IR remote (If you buy a kit without batteries, you will need to prepare a CR2025 coin cell battery on your own)
- (1) x 830 Tie Points Breadboard
- (3) x M-M wires (Female to Male Jumper Wires))

Component Introduction

IR RECEIVER SENSOR:

IR detectors are little microchips with a photocell that are tuned to listen to infrared light. They are almost always used for remote control detection - every TV and DVD player has one of these in the front to listen for the IR signal from the clicker. Inside the remote control is a matching IR LED, which emits IR pulses to tell the TV to turn on, off or change channels. IR light is not visible to the human eye, which means it takes a little more work to test a setup.

There are a few difference between these and say a CdS Photocells:

IR detectors are specially filtered for IR light, they are not good at detecting visible light. On the other hand, photocells are good at detecting yellow/green visible light, and are not good at IR light.

IR detectors have a demodulator inside that look for modulated IR at 38 KHz. Just shining an IR LED won't be detected, it has to be PWM blinking at 38KHz. Photocells do not have any sort of demodulator and can detect any frequency (including DC) within the response speed of the photocell (which is about 1KHz) IR detectors are digital out - either they detect 38KHz IR signal and output low (0V) or they do not detect any and output high (5V). Photocells act like resistors, the resistance changes depending on how much light they are exposed to.

What You Can Measure

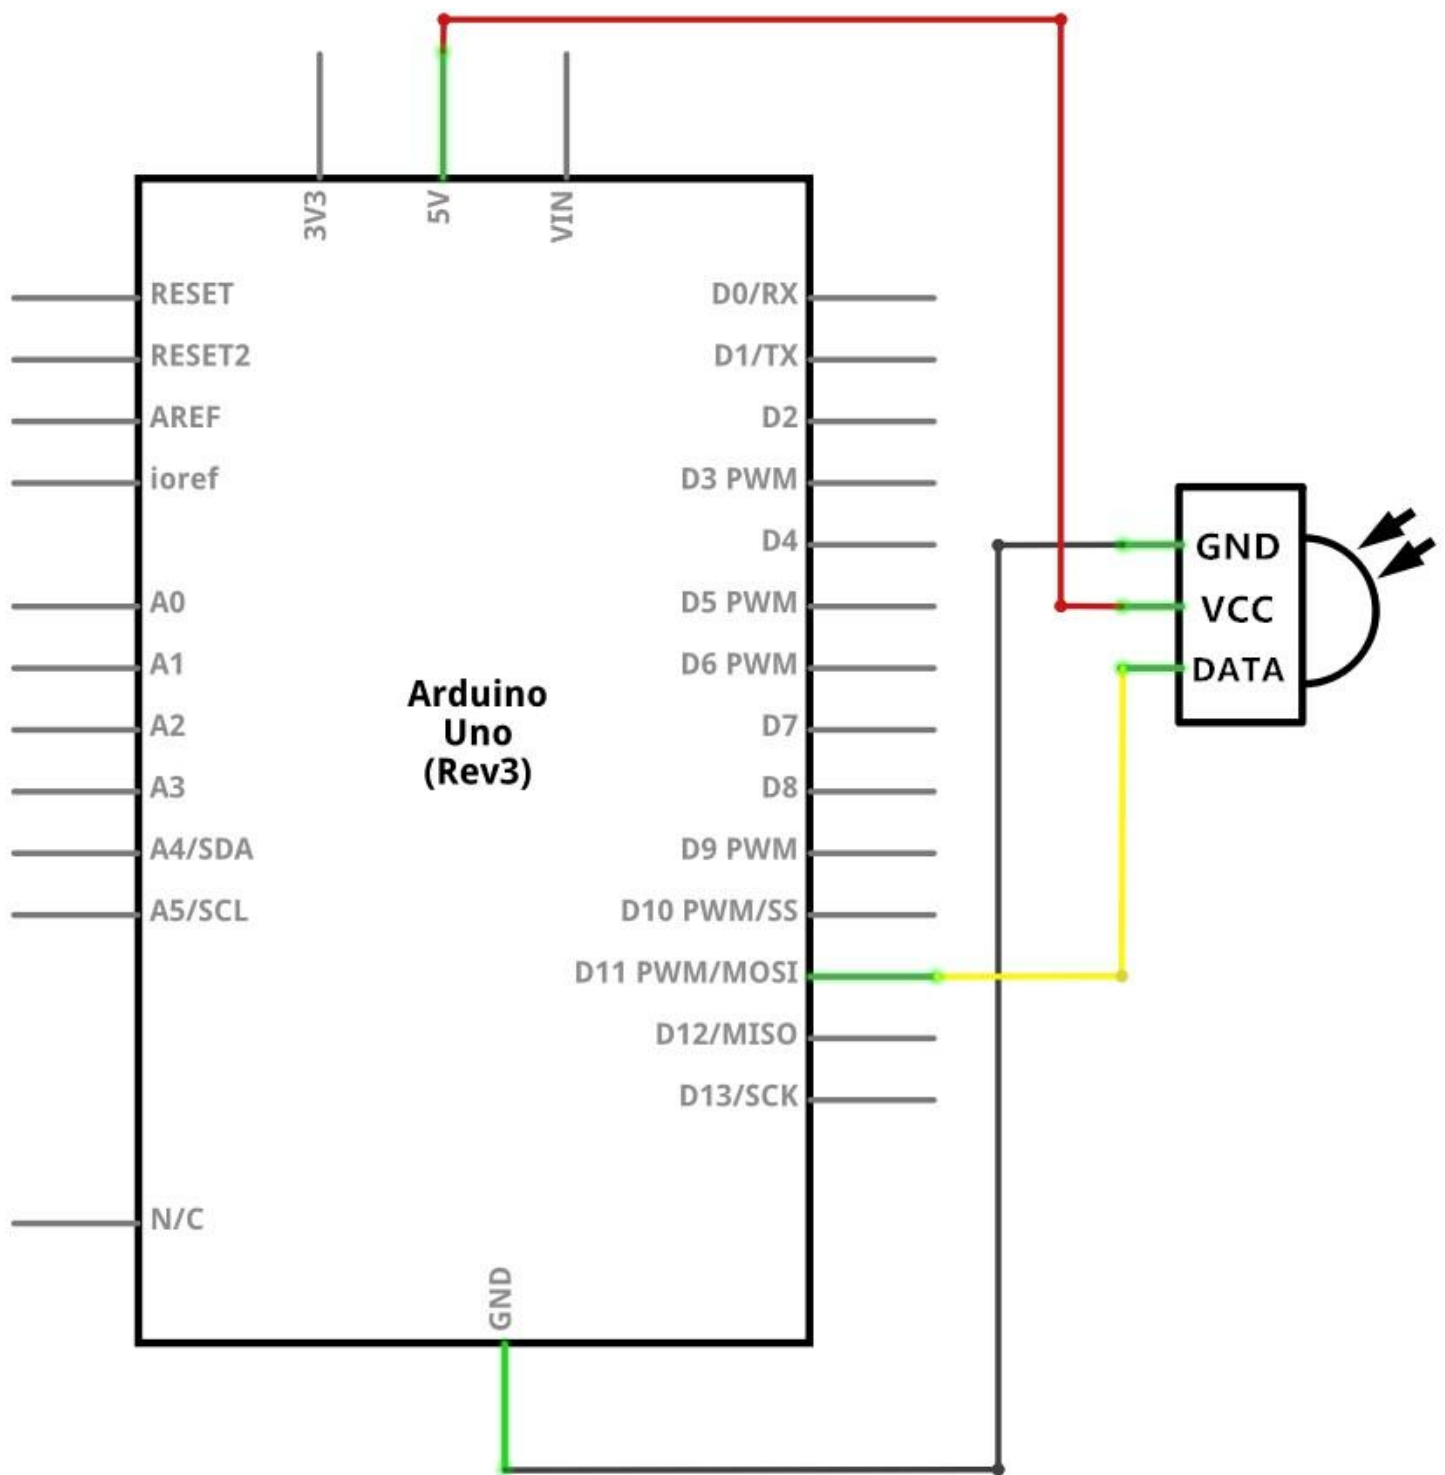

As you can see from these data sheet graphs, the peak frequency detection is at 38 KHz and the peak LED color is 940 nm. You can use from about 35 KHz to 41 KHz but the sensitivity will drop off so that it won't detect as well from afar. Likewise, you can use 850 to 1100 nm LEDs but they won't work as well as 900 to 1000nm so make sure to get matching LEDs! Check the data sheet for your IR LED to verify the wavelength.

Try to get a 940nm - remember that 940nm is not visiblelight!

Connection

Schematic

Wiring diagram

The IR receiver header has three pins as shown below:

There are 3 connections to the IR Receiver.

The connections are: Signal, Voltage and Ground.

The “GND” is the Ground, “VOUT” is signal, and “VCC” pin is Voltage 5V.

Code

After wiring, please open the program in the code folder- Lesson 14 IR Receiver Module and click UPLOAD to upload the program. See Lesson 2 for details about program uploading if there are any errors.

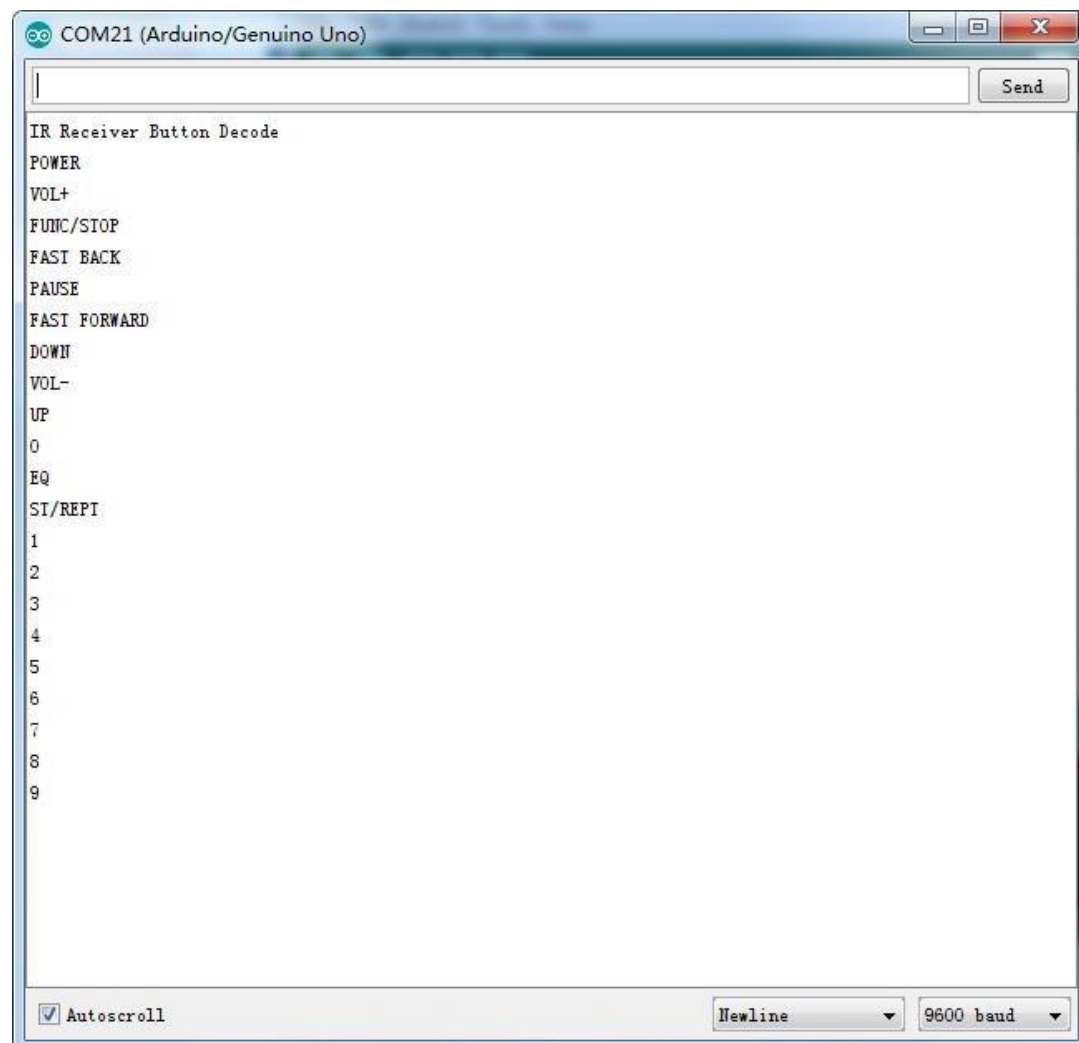

Before you can run this, make sure that you have installed the < IRremote > library or re-install it, if necessary. Otherwise, your code won't work.

For details about loading the library file, see Lesson1.

Next we will move the <RobotIRremote> out of the Library folder, we do this because that library conflicts with the one we will be using. You can just drag it back inside the library folder once you are done programming your micro controller. Once you have installed the Library, just go ahead and restart your IDE Software.

Open the monitor then you can see the data as blow:

Click the Serial Monitor button to turn on the serial monitor. The basics about the serial monitor are introduced in details in Lesson1.

Lesson 14 LED Dot Matrix Display

Overview

In the previous lessons, we learned the basic principles of the LED and digital tube. In this section, we will learn the 8*8 LED Matrix. The dot-matrix and the digital tube, LED have something in common because they are all LED. From the previous study, we know that the digital tube can display different numbers, but if we want to show all kinds of patterns, the digital tube can not reach our target, and we need the LED matrix instead. When you walk down the street, the various LED neon billboards you see are N x N dots. Now we show the information below.

Component Required:

- (1) x KUONGSHUN UNO R3
- (1) x 8x8 Red 64 LED Dot Matrix Displays
- (16) x F-M wires (Female to Male DuPont wires)

Component Introduction

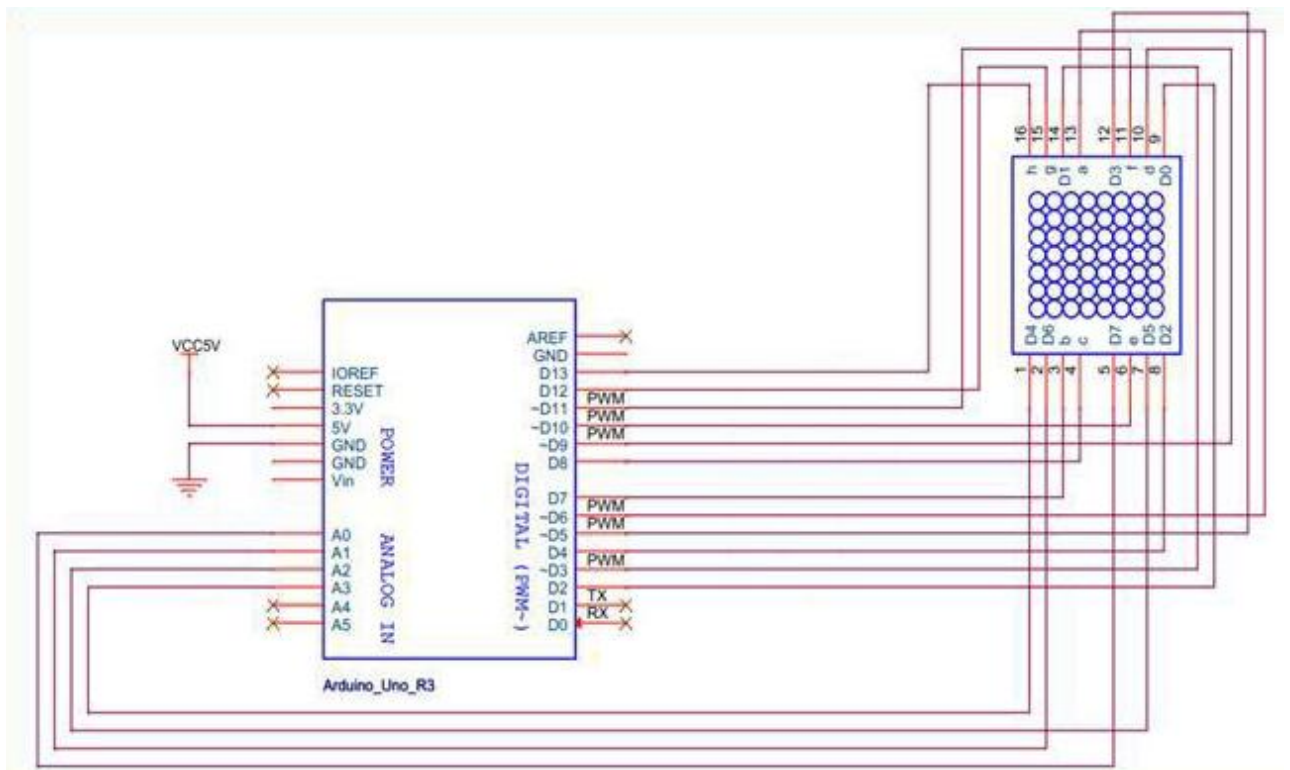

8*8 LED Dot Matrix Display

For 8x8 dot matrix, there are 16-pin dot matrix and 24-pin dot matrix according to common pin definitions, and only 16 pins are required for control of 8 x 8 columns.

The following is a pinout of the 8x8 dot matrix in our kit. The monochrome dot matrix does not differentiate between common cathode and common sun types. The blacked out LED is the positive terminal.

Connection Schematic

Wiring diagram

Code

Program Interpretation : Open the code. Define the pins corresponding to each row and column, and then assign the corresponding pins to them. When displaying multiple lines, the line scanning method is used to define the display time of each line in the delay function, which can be adjusted according to the display effect.

Lesson 15 LM35 Temperature Sensor

Overview

In this course, we will use the LM35 module to obtain the temperature value of the environment.

Component Required:

- (1) x KUONGSHUN UNO R3
- (1) x LM35 Temperature Sensor
- (1) x 830 Tie Points Breadboard
- (5) x M-M wires (Male to Male Jumper wires)

Component Introduction Thermistor

LM35 Temperature Sensor:

The LM35 is a widely used temperature sensor. Because it utilizes internal compensation, the output can start at 0°C. The LM35 can be calibrated to achieve 1/4C accuracy at room temperature without additional calibration.

At room temperature, the LM35 can achieve 1/4C accuracy without additional calibration. Its power supply mode has a single power supply and positive and negative dual power supply two kinds of pins as shown in Figure 1, positive and negative dual power supply mode can provide negative temperature measurement; two kinds of connection method of quiescent current - temperature relationship, in the quiescent temperature in the self-heating effect of the low (0.08 °), a single power supply mode in the 25 under the quiescent current of about 50uA, the operating voltage is wider, can be in the 4-20V supply voltage range of normal operation is very Power saving.

Formula: $V_{\text{out_LM35}}(T) = 10^{\text{mV}} / ^{\circ}\text{C} \times T^{\circ}\text{C}$

Working voltage: DC2.7~12V

Function description: AM312 human body sensing module is a digital intelligent automatic control product based on passive human body infrared technology. It has high sensitivity and strong reliability and is widely used in various automatic inductive electrical equipment.

Product features:

The anti-interference is enhanced, and digital signal processing is used internally to directly output high and low levels.

Repeatable trigger mode: that is, after the induction output of high level, if a human body moves in its sensing range during the delay period, its output will remain high level until the time delay after the person leaves (that is, the induction module will automatically delay a delay period after detecting each activity of the human body, and the time of the last activity is the starting point of the delay time).

Technical parameters:

- 1、 Working voltage: DC 4~30V
- 2、 Working current: less than 133μA
- 3、 Output Voltage: +6V~-1.0V
- 4、 Output impedance: 0.1Ω at 1mA load
- 5、 Accuracy: 0.5 °C accuracy (at +25 °C)
- 6、 leakage current: less than 60μA
- 7、 Contrast factor: linear +10.0mV / °C
- 8、 Non-linear value: ±1/4°C
- 9、 Calibration method: Direct calibration with camera temperature
- 10、 Rated temperature range: -55 to +150°C.

Wiring diagram

Lesson 16 Water Level Detection Sensor Module

Overview

In this lesson, you will learn how to use a water level detection sensor module. This module can perceive the depth of water and the core component is an amplifying circuit which is made up of a transistor and several pectinate PCB routings. When put into the water, these routings will present a resistor that can change along with the change of the water's depth. Then, the signal of water's depth is converted into the electrical signal, and we can know the change of water's depth through the ADC function of UNO R3.

Component Required:

- (1) x KUONGSHUN UNO R3
- (3) x F-M wires (Female to Male DuPont wires)
- (1) x Water level detection sensor module

Component Introduction

Water sensor:

A water sensor brick is designed for water detection, which can be widely used in sensing the rainfall, water level, even the liqueate leakage. The brick is mainly composed of three parts: an electronic brick connector, a 1 M Ω resistor, and several lines of bare conducting wires.

This sensor workKUONGSHUN by having a series of exposed traces connected to ground. Interlaced between the grounded traces are the sensetraces.

The sensor traces have a weak pull-up resistor of 1 M Ω . The resistor will pull the sensor trace value high until a drop of water shorts the sensor trace to the grounded trace. Believe it or not this circuit will work with the digital I/O pins of your UNO R3 board or you can use it with the analog pins to detect the amount of water induced contact between the grounded and sensortraces.

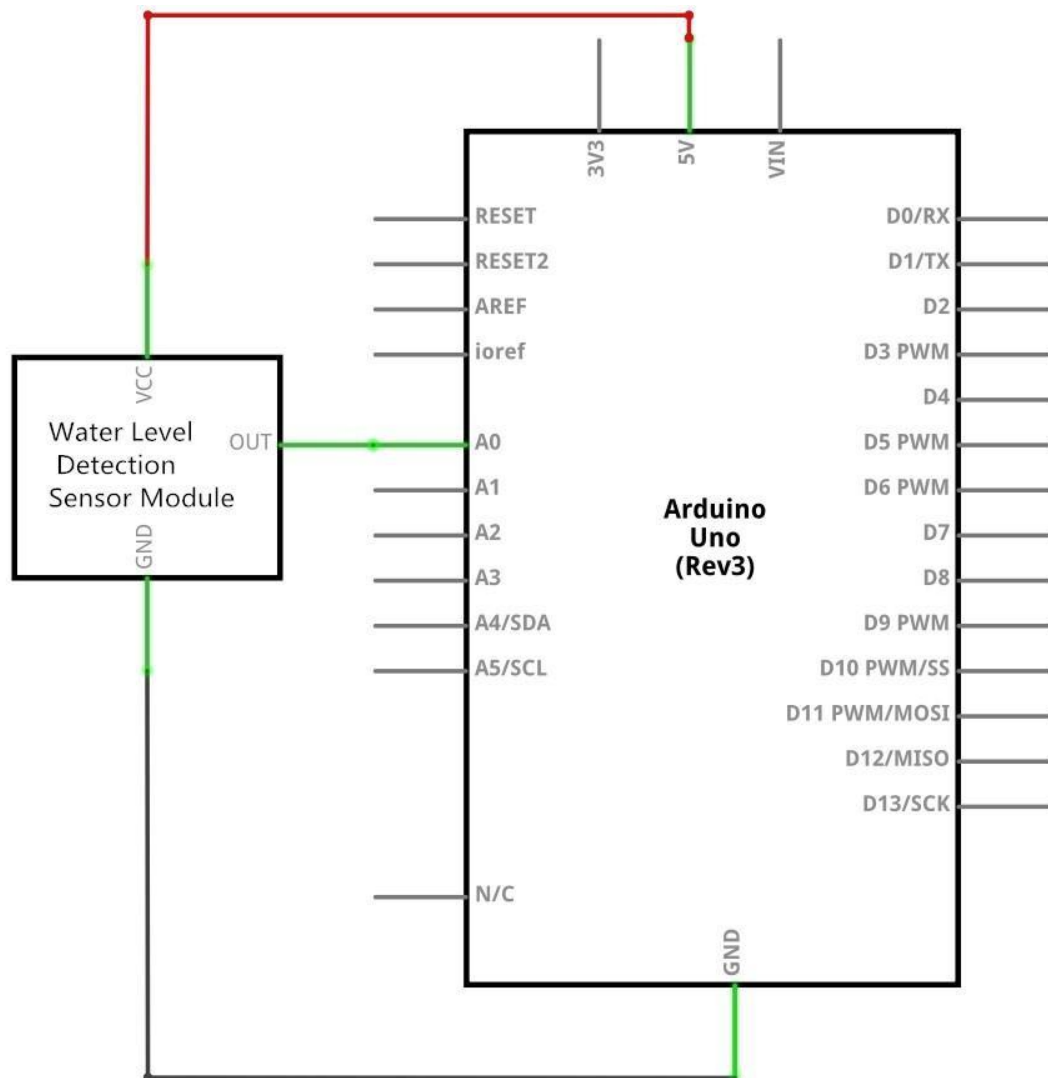

This item can judge the water level through with a series of exposed parallel wires stitch to measure the water droplet/water size. It can easily change the water size to analog signal, and output analog value can directly be used in the program function, then to achieve the function of water levelalarm.

It has low power consumption, and high sensitivity. Features:

- 1、 Working voltage: 5V
- 2、 Working Current: <20ma 3、 Interface: Analog
- 4、 Width of detection: 40mm×16mm
- 5、 Working Temperature: 10°C~30°C 6、 Output voltage signal: 0~4.2V

Connection

Schematic

Wiring diagram

Wiring tips: Power supply (+) is connected to 5V of UNO R3 board, ground electrode (-) is connected to GND. Signal output (S) is connected to the ports (A0-A5) which have function of inputting analog signal in UNO R3 board, random one is OK, but it should define the same demo code as the routine.

Code

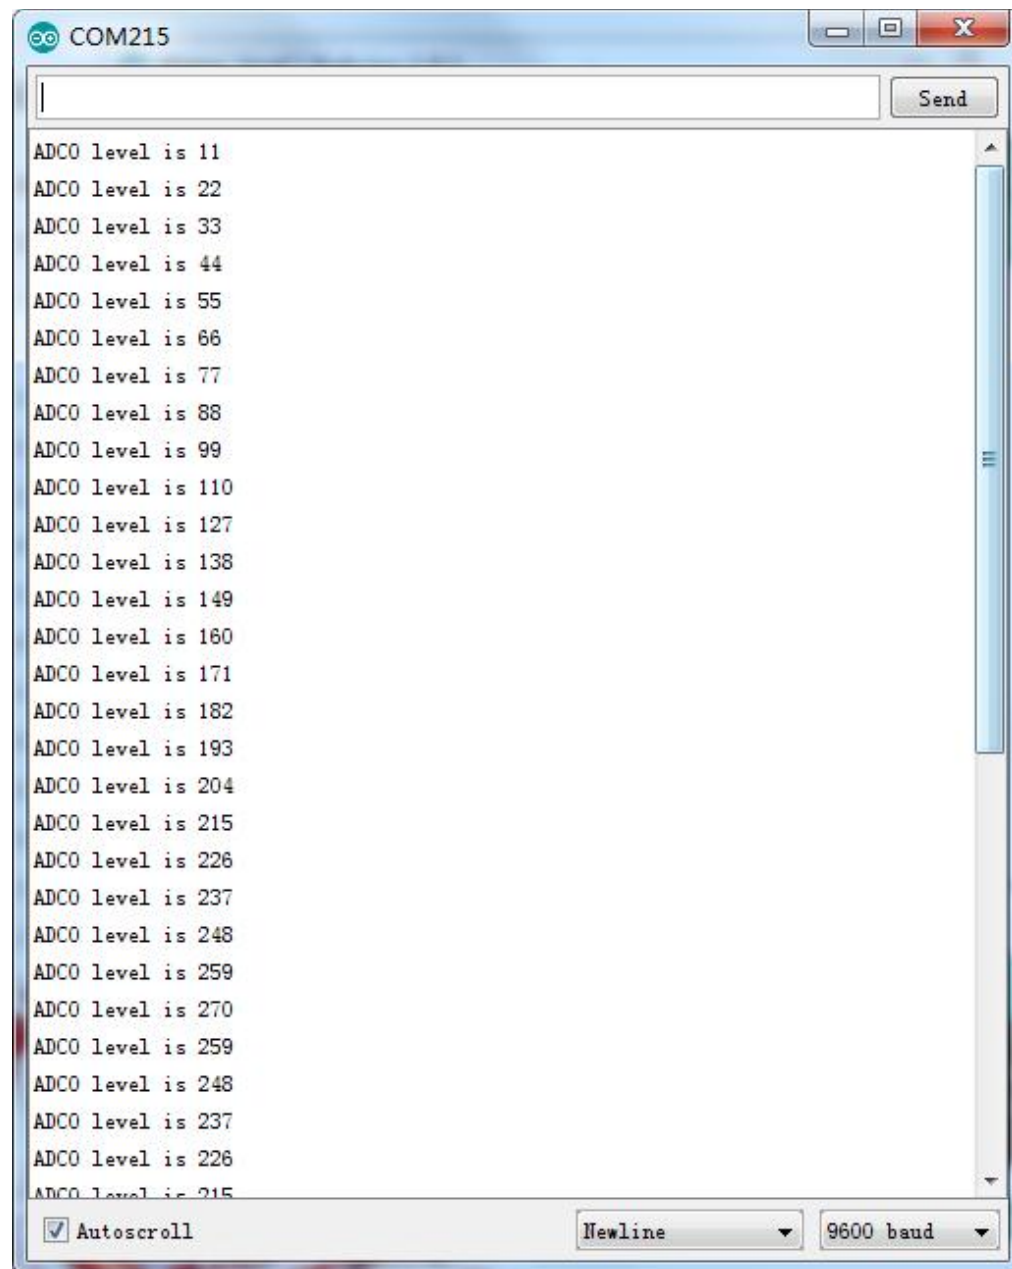

After wiring, please open the program in the code folder- Lesson 18 Water Level Detection Sensor Module and click UPLOAD to upload the program. See Lesson 2 for details about program uploading if there are any errors.

Example picture

Open the monitor then you can see the data as below:

Click the Serial Monitor button to turn on the serial monitor. The basics about the serial monitor are introduced in details in Lesson1.

Lesson 17 Real Time Clock Module

Overview

In this lesson, you will learn how to use the RTC module, The DS1302 real-time clock is a low-power chip.

Component Required:

(1) x KUONGSHUN UNO R3

(1) x DS1302 RTC module (If you buy a kit without batteries, you will need to prepare a CR2025 coin cell battery on your own)

(5) x F-M wires (Female to Male DuPont wires)

Component Introduction

DS1302

DS1302 is a high-performance, low-power real-time clock chip, real-time clock can provide seconds, minutes, hours, days, weeks, months and years, a month less than 31 days can be automatically adjusted, and has a leap year compensation function. The operating voltage is as wide as 2.5~5.5 V. It adopts dual power supply (main power supply and backup power supply), and can be set up to charge the backup power supply, which provides the ability to charge the backup power supply with trickle current.

Wiring diagram

Open the monitor then you can see the module can read the time as below:

[Click the Serial Monitor button](#) to turn on the serial monitor. The basics about the serial monitor are introduced in details detail in Lesson1.

Lesson 18 Sound Sensor Module

Overview

In this lesson, you will learn how to use a sound sensor module. This module has two outputs:

AO: analog output, real-time output voltage signal of microphone

DO: when the intensity of the sound reaches a certain threshold, the output is a high or low level signal. The threshold sensitivity can be achieved by adjusting the potentiometer.

To make sure the microphone can detect your voice normally, please try to change its sensitivity by turning the blue precise potentiometer on the module. Given to its preciseness, it takes at least 10 circles for you to get some response.

- 1.DO:digital output
- 2.VCC: 3.3V-5V DC
- 3.GND:ground
- 4.AO:analog output

Component Required:

- (1) x KUONGSHUN UNO R3
- (1) x Sound sensor module
- (4) x F-M wires (Female to Male DuPont wires)

Component Introduction

Microphone

Transducers are devices which convert energy from one form to other. A microphone is a transducer which converts sound energy to electrical signals. It workKUONGSHUN opposite to a speaker. Microphones are available in different shapes and sizes. Depending on the application, a microphone may use different technologies to convert sound to electrical signals. Here, we are going to discuss about the electret condenser microphone which is widely used in mobile phones, laptops, etc.

As the name suggests, the electret condenser microphone is a parallel plate

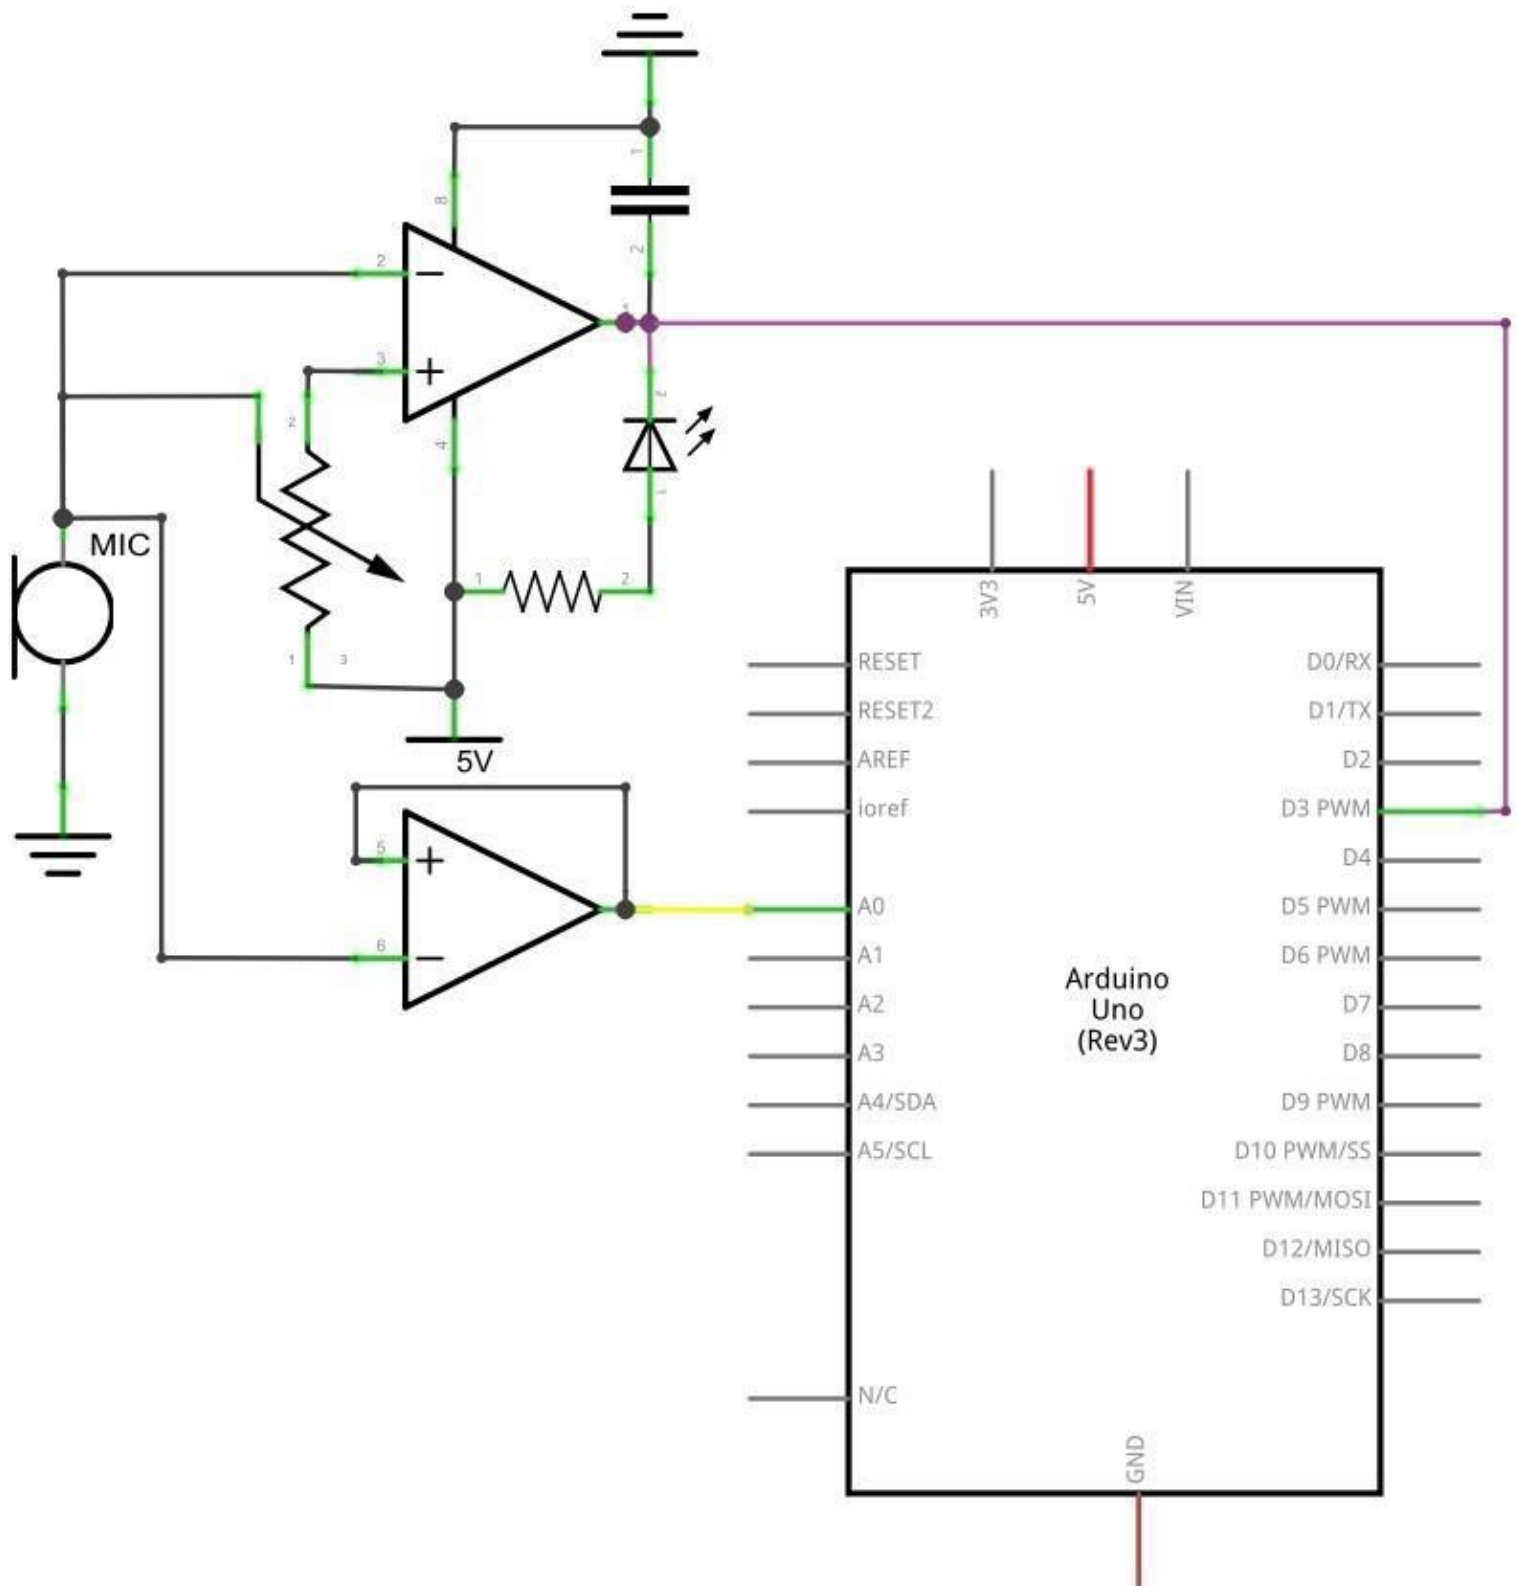

capacitor and work on the principle of a variable capacitance. It consists of two plates, one fixed (called the back plate) and the other moveable (called the diaphragm) with a small gap between them. An electric potential charges the plate. When sound strikes the diaphragm it starts moving, thereby changing the capacitance between the plates which in turn results in a variable electric current to flow.

These microphones are widely used in electronic circuits to detect minor sounds or air vibrations which in turn are converted to electrical signals for further use. The two legs as shown in the image above are used to make electrical connection with the circuit.

A solid conducting metal body encapsulates the various parts of the microphone. The top face is covered with a porous material with the help of glue. It acts as a filter for the dust particles. The sound signals/air vibrations passes through the porous material and falls on the diaphragm through the hole shown in the image above.

Connection**Schematic**

Wiring diagram

The code

After wiring, please open the program in the code folder- Lesson 20 Sound Sensor Module and click UPLOAD to upload the program. See Lesson 2 for details about program uploading if there are any errors.

This module provides two signal output modes, for which we wrote two codes: **digital_signal_output** and **analog_signal_output**. The code of **digital_signal_output** work when the voice reaches a certain value, it will trigger a digital signal and the dig #11 pin on Arduino will output a high level and the indicator L will be lit up at the same time. This triggering value may be changed according to the sensitivity adjustment method mentioned above. The code of **analog_signal_output** will read the analog value of the module and directly display it on the serial monitor, likewise, this value can also be changed according to the sensitivity adjustment method mentioned above.

Example

Open the monitor then you can see the data asbelow:

Click the Serial Monitor button to turn on the serial monitor. The basics about the serial monitor are introduced in details in Lesson 1.

Lesson 19 RC522 RFID Module

Overview

In this lesson, you will learn to how to apply the RC522 RFID Reader Module on UNO R3. This module uses the Serial Peripheral Interface (SPI) bus to communicate with controllers such as Arduino, Raspberry Pi, beagle board, etc.

Component Required:

- (1) x KUONGSHUN UNO R3
- (1) x RC522 RFID module
- (7) x F-M wires (Female to Male DuPont wires)

Component Introduction

RC522

The MFRC522 is a highly integrated reader/writer for contactless communication at 13.56 MHz. The MFRC522 reader supports ISO 14443A / MIFARE® mode.

The MFRC522's internal transmitter part is able to drive a reader/writer antenna designed to communicate with ISO/IEC 14443A/MIFARE® cards and transponders without additional active circuitry. The receiver part provides a robust and efficient implementation of a demodulation and decoding circuitry for signals from ISO/IEC 14443A/MIFARE® compatible cards and transponders. The digital part handles the complete ISO/IEC 14443A framing and error detection (Parity & CRC).The MFRC522 supports MIFARE®Classic (e.g. MIFARE® Standard) products. The MFRC522 supports contactless communication using MIFARE® higher transfer speeds up to 848 kbit/s in both directions.

Various host interfaces are implemented:

- SPI interface
- Serial UART (similar to RS232 with voltage levels according pad voltage supply)
- I2C interface.

The figure below shows a typical circuit diagram, using a complementary antenna connection to the MFRC522.

Connection

Schematic

Wiring diagram

Code

After wiring, please open the program in the code folder- Lesson 21 RC522 RFID Module and press UPLOAD to upload the program. See Lesson 2 for details about program uploading if there are any errors.

Before you can run this, make sure that you have installed the < rfid > library or re- install it, if necessary. Otherwise, your code won't work.

For details about loading the library file, see Lesson 1.

Lesson 20 LCD Display

Overview

In this lesson, you will learn how to wire up and use an alphanumeric LCD display. The display has an LED backlight and can display two rows with up to 16 characters on each row. You can see the rectangles for each character on the display and the pixels that make up each character. The display is just white on blue and is intended for showing text.

In this lesson, we will run the Arduino example program for the LCD library, but in the next lesson, we will get our display to show the temperature, using sensors.

Component Required:

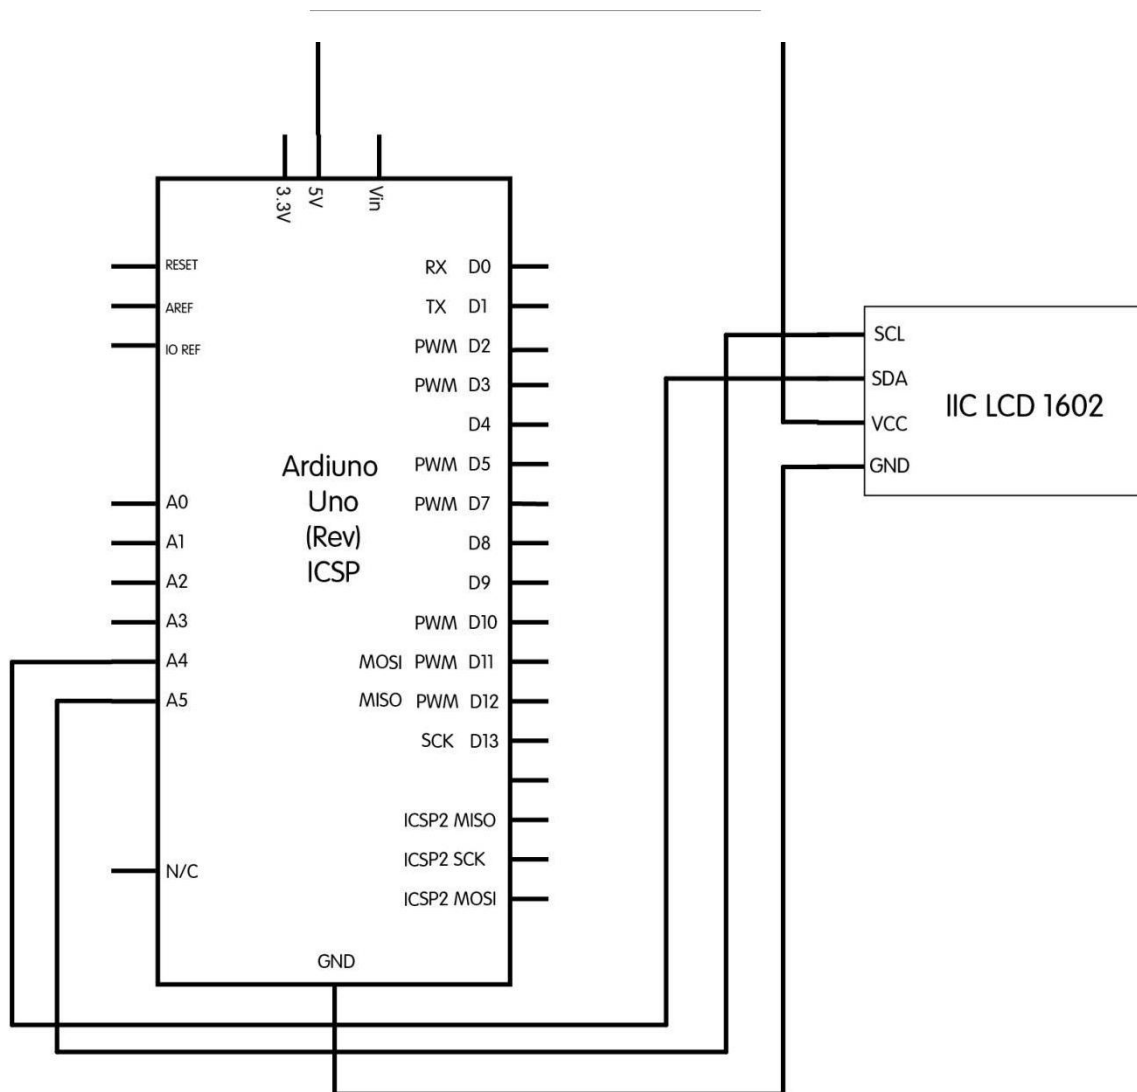

- (1) x KUONGSHUN UNO 2560
- (1) x LCD1602 I2C module
- (4) x F-M wires (Female to Male Dupond wires)

Component Introduction

LCD1602

This is great LCD display compatible with arduino. With limited pin resources, your project will quickly run out of resources using normal LCDs. With this I2C interface LCD module, you only need 2 lines (I2C) to display the information. If you already have I2C devices in your project, this LCD module actually cost no more resources at all. The address can be set 0x27.

Connection Schematic

Wiring diagram

Code

After wiring, please open the program in the code folder- Lesson 20 LCD Display and click UPLOAD to upload the program. See Lesson 2 for details about program uploading if there are any errors.

Before you can run this, make sure that you have installed the < LiquidCrystal_I2C > library or re-install it, if necessary. Otherwise, your code won't work.

For details about loading the library file, see Lesson 1.

Upload the code to your Arduino board and you should see the message

“ Hello, world!

KUONGSHUN”

displayed.

The first thing of note in the sketch is the line:

```
#include <LiquidCrystal_I2C.h>
```

This tells Arduino that we wish to use the LiquidCrystal_I2C library.

Next set the LCD address to 0x27 for a 16 chars and 2 line display

```
LiquidCrystal_I2C lcd(0x27,16,2); //
```

After uploading this code, make sure the backlight is lit up, and adjust the potentiometer all the way around until you see the text message

In the 'setup' function, we have four commands:

```
lcd.setCursor(0,0);
```

```
lcd.print("Hello, world!");
```

```
lcd.setCursor(0,1);
```

```
lcd.print("KUONGSHUN");
```

The `lcd.setCursor(0,0)` tells the Begin displaying the next line of code in the first row and first column.

The `lcd.setCursor(0,1)` tells the Begin displaying the next line of code in the second row and first column.

```
lcd.print("Hello, world!");
```

```
lcd.print("KUONGSHUN");
```

Tell screen display

“ Hello, world!

KUONGSHUN”

Example picture

Lesson 21 Eight LED with 74HC595

Overview

In this lesson, you will learn how to use eight large red LEDs with an UNO without needing to give up 8 output pins!

Although you could wire up eight LEDs each with a resistor to an UNO pin you would rapidly start to run out of pins on your UNO. If you don't have a lot of stuff connected to your UNO. It's OK to do so - but often times we want buttons, sensors, servos, etc. and before you know it you've got no pins left. So, instead of doing that, you are going to use a chip called the 74HC595 Serial to Parallel Converter. This chip has eight outputs (perfect) and three inputs that you use to feed data into it a bit at a time.

This chip makes it a little slower to drive the LEDs (you can only change the LEDs about 500,000 times a second instead of 8,000,000 a second) but it's still really fast, way faster than humans can detect, so it's worth it!

Component Required:

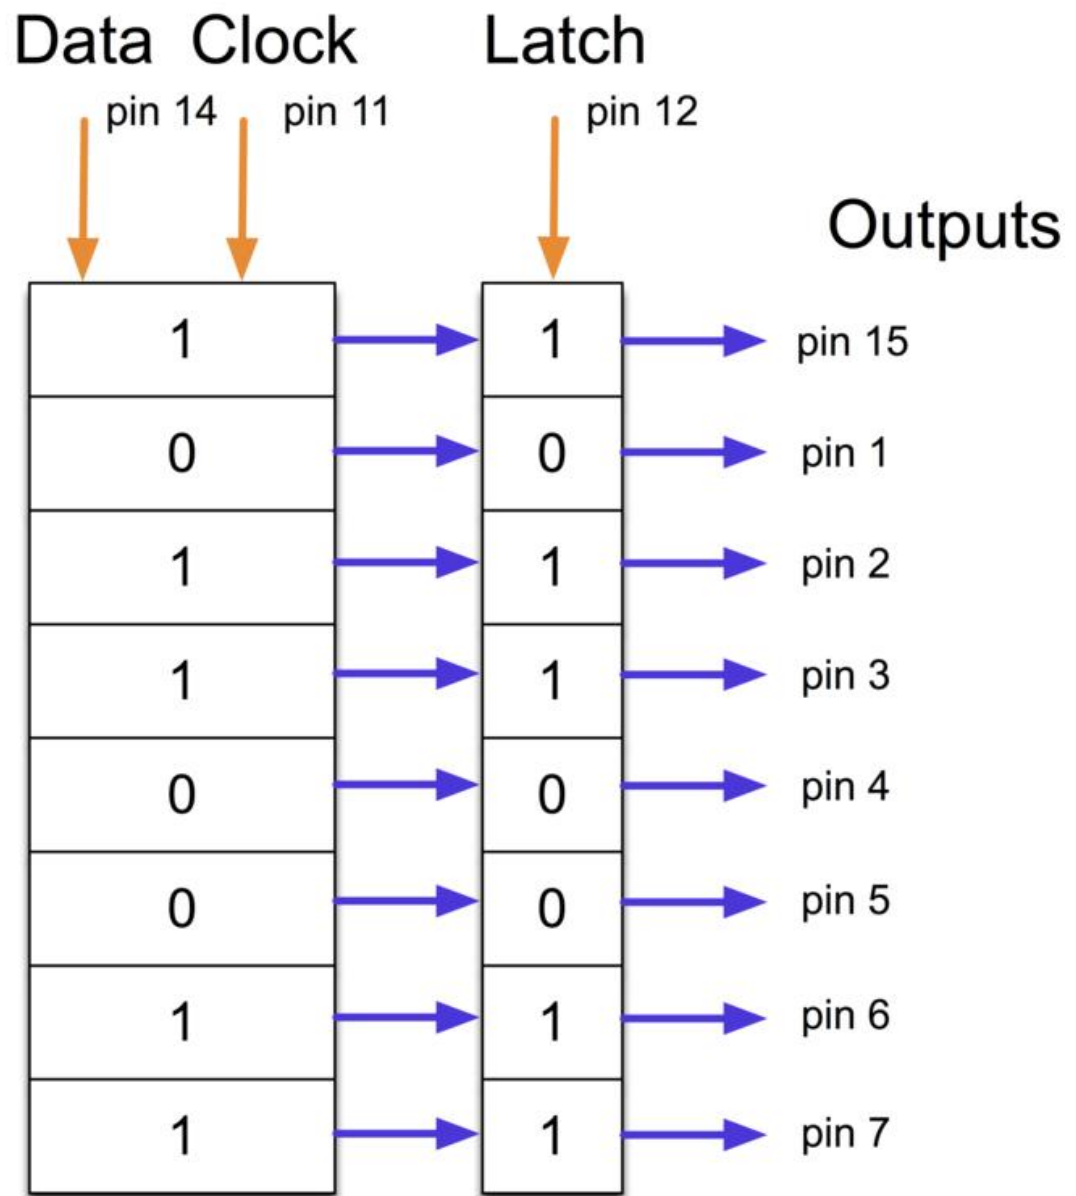

- (1) x KUONGSHUN UNO R3
- (1) x 830 tie-points breadboard
- (8) x leds
- (8) x 220 ohm resistors
- (1) x 74hc595 IC
- (14) x M-M wires (Male to Male jumperwires)

Component Introduction

74HC595 Shift Register:

The shift register is a type of chip that holds what can be thought of as eight memory locations, each of which can either be a 1 or a 0. To set each of these values on or off, we feed in the data using the 'Data' and 'Clock' pins of the chip.

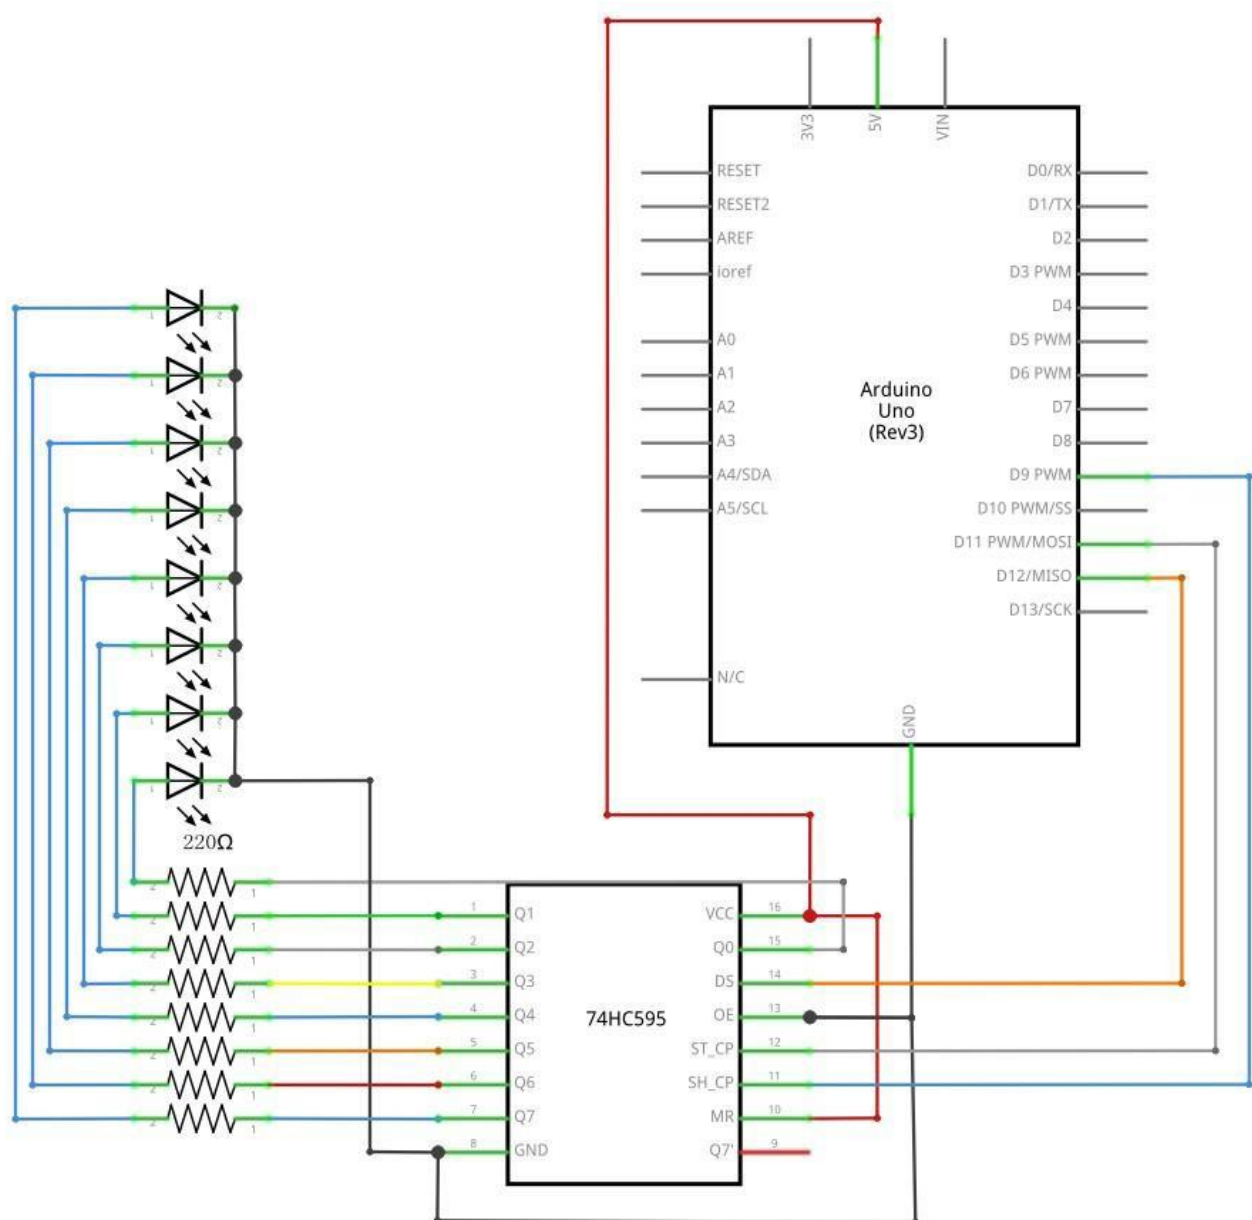

The clock pin needs to receive eight pulses. At each pulse, if the data pin is high, then a 1 gets pushed into the shift register; otherwise, a 0. When all eight pulses have been received, enabling the 'Latch' pin copies those eight values to the latch register. This is necessary; otherwise, the wrong LEDs would flicker as the data is being loaded into the shift register.

The chip also has an output enable (OE) pin, which is used to enable or disable the outputs all at once. You could attach this to a PWM-capable UNO pin and use 'analogWrite' to control the brightness of the LEDs. This pin is active low, so we tie it to GND.

Connection

Schematic

Wiring diagram

As we have eight LEDs and eight resistors to connect, there are actually quite a few connections to be made. It is probably easiest to put the 74HC595 chip in first, as pretty much everything else connects to it. Put it so that the little U-shaped notch is towards the top of the breadboard. Pin 1 of the chip is to the left of this notch.

Digital 12 from the UNO goes to pin #14 of the shift register Digital 11 from the UNO goes to pin #12 of the shift register Digital 9 from the UNO goes to pin #11 of the shift register

All but one of the outputs from the IC is on the left side of the chip. Hence, for ease of connection, that is where the LEDs are, too.

After the chip, put the resistors in place. You need to be careful that none of the leads of the resistors are touching each other. You should check this again before you connect the power to your UNO. If you find it difficult to arrange the resistors without their leads touching, then it helps to shorten the leads so that they are lying closer to the surface of the breadboard.

Next, place the LEDs on the breadboard. The longer positive LED leads must all be towards the chip, whichever side of the breadboard they are on.

Attach the jumper leads as shown above. Do not forget the one that goes from pin 8 of the IC to the GND column of the breadboard.

Load up the sketch listed a bit later and try it out. Each LED should light in turn until all the LEDs are on, and then they all go off and the cycle repeats.

Code

After wiring, please open the program in the code folder- Lesson 24 Eight LED with 74HC595 and click UPLOAD to upload the program. See Lesson 2 for details about program uploading if there are any errors.

The first thing we do is define the three pins we are going to use. These are the UNO digital outputs that will be connected to the latch, clock and data pins of the 74HC595.

```
int latchPin = 11; int clockPin = 9; int dataPin = 12;
```

Next, a variable called 'leds' is defined. This will be used to hold the pattern of which LEDs are currently turned on or off. Data of type 'byte' represents numbers using eight bits. Each bit can be either on or off, so this is perfect for keeping track of

which of our eight LEDs are on or off. `byte leds = 0;`

The 'setup' function just sets the three pins we are using to be digital outputs. `void setup()`

```
{  
pinMode(latchPin, OUTPUT); pinMode(dataPin, OUTPUT); pinMode(clockPin, OUTPUT);  
}
```

The 'loop' function initially turns all the LEDs off, by giving the variable 'leds' the value 0. It then calls 'updateShiftRegister' that will send the 'leds' pattern to the shift register so that all the LEDs turn off. We will deal with how 'updateShiftRegister' works later.

The loop function pauses for half a second and then begins to count from 0 to 7 using the 'for' loop and the variable 'i'. Each time, it uses the Arduino function 'bitSet' to set the bit that controls that LED in the variable 'leds'. It then also calls 'updateShiftRegister' so that the leds update to reflect what is in the variable 'leds'. There is then a half second delay before 'i' is incremented and the next LED is lit. `void loop()`

```
{  
leds = 0; updateShiftRegister(); delay(500);  
for (int i = 0; i < 8; i++)  
{  
bitSet(leds, i); updateShiftRegister(); delay(500);  
}  
}
```

The function 'updateShiftRegister', first of all sets the latchPin to low, then calls the UNO function 'shiftOut' before putting the 'latchPin' high again. This takes four parameters, the first two are the pins to use for Data and Clock respectively.

The third parameter specifies which end of the data you want to start at. We are going to start with the right most bit, which is referred to as the 'Least Significant

Bit' (LSB).

The last parameter is the actual data to be shifted into the shift register, which in this case is 'leds'.

```
void updateShiftRegister()  
{  
  digitalWrite(latchPin, LOW); shiftOut(dataPin, clockPin, LSBFIRST, leds); digitalWrite(latchPin, HIGH);  
}
```

If you wanted to turn one of the LEDs off rather than on, you would call a similar Arduino function (bitClear) with the 'leds' variable. This will set that bit of 'leds' to be 0 and you would then just need to follow it with a call to 'updateShiftRegister' to update the actual LEDs.

Example

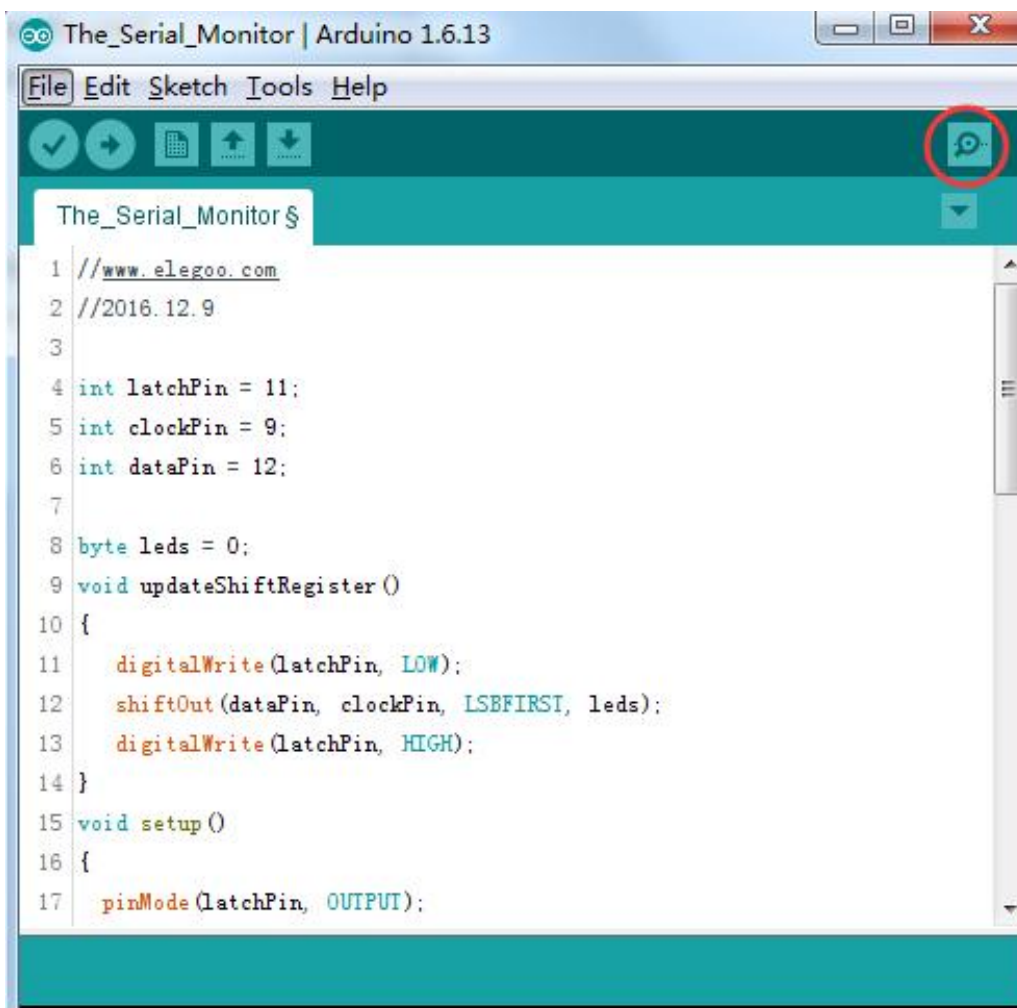

Lesson 22 The Serial Monitor

Overview

In this lesson, you will build on Lesson 24, adding the facility to control the LEDs from your computer using the Arduino Serial Monitor. The serial monitor is the 'tether' between the computer and your UNO. It lets you send and receive text messages, handy for debugging and also controlling the UNO from a keyboard! For example, you will be able to send commands from your computer to turn on LEDs. In this lesson, you will use exactly the same parts and a similar breadboard layout as Lesson 24. So, if you have not already done so, follow Lesson 24 now.

Steps taken

After you have uploaded this sketch onto your UNO, click on the right-most button on the toolbar in the Arduino IDE. The button is circled below.

The following window will open.

Click the Serial Monitor button to turn on the serial monitor. The basics about the serial monitor are introduced in details in Lesson 1.

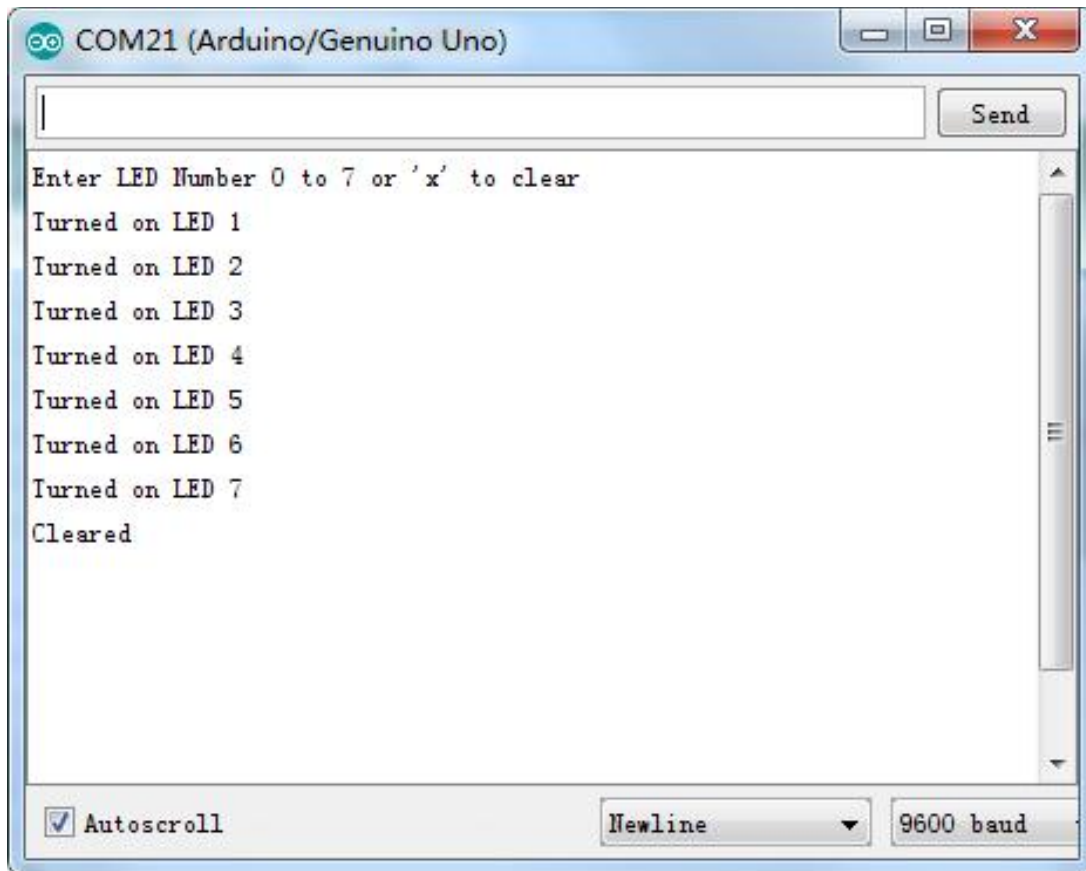

This window is called the Serial Monitor and it is part of the Arduino IDE software. Its job is to allow you to both send messages from your computer to an UNO board (over USB) and also to receive messages from the UNO.

The message “Enter LED Number 0 to 7 or 'x' to clear” has been sent by the Arduino. It is telling us what commands we can send to the Arduino: either send the 'x' (to turn all the LEDs off) or the number of the LED you want to turn on (where 0 is the bottom LED, 1 is the next one up, all the way to 7 for the top LED).

Try typing the following commands into the top area of the Serial Monitor that is level with the 'Send' button. Press 'Send', after typing each of these characters: x 0 3 5

Typing x will have no effect if the LEDs are already all off, but as you enter each number, the corresponding LED should light and you will get a confirmation message from the UNO board. The Serial Monitor will appear as shown below.

Type x again and press 'Send' to turn off all LEDs.

Code

After wiring, please open program in the code folder- Lesson 25 The Serial Monitor and click **UPLOAD** to upload the program. See Lesson 2 for details about program uploading if there are any errors.

As you might expect, the sketch is based on the sketch used in Lesson 24. So, we will just cover the new bits here. You will find it useful to refer to the full sketch in your Arduino IDE.

In the 'setup' function, there are three new lines at the end: `void setup()`

```
{  
pinMode(latchPin, OUTPUT); pinMode(dataPin, OUTPUT); pinMode(clockPin, OUTPUT);  
updateShiftRegister(); Serial.begin(9600);
```

```
while (! Serial); // Wait until Serial is ready - Leonardo Serial.println("Enter LED Number 0 to 7 or 'x' to clear");  
}
```

Firstly, we have the command 'Serial.begin(9600)'. This starts serial communication, so that the UNO can send out commands through the USB connection. The value 9600 is called the 'baud rate' of the connection. This is how fast the data is to be sent. You can change this to a higher value, but you will also have to change the Arduino Serial monitor to the same value. We will discuss this later; for now, leave it at 9600.

The line beginning with 'while' ensures that there is something at the other end of the USB connection for the Arduino to talk to before it starts sending messages. Otherwise, the message might be sent, but not displayed. This line is actually only necessary if you are using an Arduino Leonardo because the Arduino UNO automatically resets the Arduino board when you open the Serial Monitor, whereas this does not happen with the Leonardo.

The last of the new lines in 'setup' sends out the message that we see at the top of the Serial Monitor.

The 'loop' function is where all the action happens: `void loop()`

```
{  
  if (Serial.available())  
  {  
    char ch = Serial.read();  
    if (ch >= '0' && ch <= '7')  
    {  
      int led = ch - '0'; bitSet(leds, led); updateShiftRegister();  
      Serial.print("Turned on LED "); Serial.println(led);  
    }  
    if (ch == 'x')  
    {  
      leds = 0; updateShiftRegister();  
      Serial.println("Cleared");  
    }  
  }  
}
```

Everything that happens inside the loop is contained within an 'if' statement. So unless the call to the built-in Arduino function 'Serial.available()' is 'true' then nothing else will happen.

Serial.available() will return 'true' if data has been sent to the UNO and is there ready to be processed. Incoming messages are held in what is called a buffer and Serial.available() returns

true if that buffer is Not empty.

If a message has been received, then it is on to the next line of code: `char ch = Serial.read();`

This reads the next character from the buffer, and removes it from the buffer. It also assigns it to the variable 'ch'. The variable 'ch' is of type 'char' which stands for 'character' and as the name suggests, holds a single character.

If you have followed the instructions in the prompt at the top of the Serial Monitor, then this character will either be a single digit number between 0 and 7 or the letter 'x'.

The 'if' statement on the next line check to see if it is a single digit by seeing if 'ch' is greater than or equal to the character '0' and less than or equal to the character '7'. It look a little strange comparing characters in this way, but is perfectly acceptable.

Each character is represented by a unique number, called its ASCII value. This means that when we compare characters using `<=` and `>=` it is actually the ASCII values that were being compared.

If the test passes, then we come to the next line: `int led = ch - '0';`

Now we are performing arithmetic on characters! We are subtracting the digit '0' from whatever digit was entered. So, if you typed '0' then '0' - '0' will equal 0. If you typed '7' then '7' - '0' will equal the number 7 because it is actually the ASCII values that are being used in the subtraction.

Since that we know the number of the LED that we want to turn on, we just need to set that bit in the variable 'leds' and update the shift register.

`bitSet(leds, led); updateShiftRegister();`

The next two lines write back a confirmation message to the Serial Monitor. `Serial.print("Turned on LED ");`
`Serial.println(led);`

The first line uses `Serial.print` rather than `Serial.println`. The different between the two is that `Serial.print` does not start a new line after printing whatever is in its parameter. We use this in the first line, because we are printing the message in two parts. Firstly the general bit: 'Turned on LED ' and then the number of the LED.

The number of the LED is held in an 'int' variable rather than being a text string. `Serial.print` can take either a text string enclosed in double-quotes, or an 'int' or for that matter pretty much any type of variable.

After the 'if' statement that handles the case, when a single digit has been handled, there is a second 'if' statement that check to see if 'ch' is the letter 'x'.

```
if (ch == 'x')
{
  leds = 0; updateShiftRegister(); Serial.println("Cleared");
}
```

If it is, then it clears all the LEDs and sends a confirmation message.

Lesson 23 Flame Sensor

Overview

In this lesson, we will make a flame alarm device using a flame sensor and a active buzzer.

Component Required:

- (1) x KUONGSHUN UNO R3
- (1) x 830 tie-points breadboard
- (1) x Flame Sensor
- (1) x Active Buzzer
- (1) x 10k ohm resistor
- (6) x M-M wires (Male to Male jumper wires)

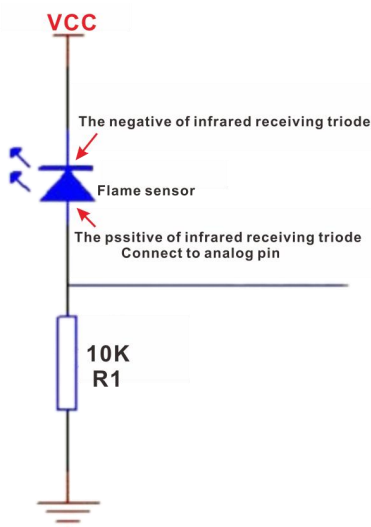

Component Introduction

PHOTOCELL:

Flame sensor is based on the principle that infrared ray is highly sensitive to flame. It has an infrared receiving tube specially designed to detect fire, and then to convert the flame brightness into fluctuating level signal. The

signals are then input into the central processor and be dealt with accordingly.

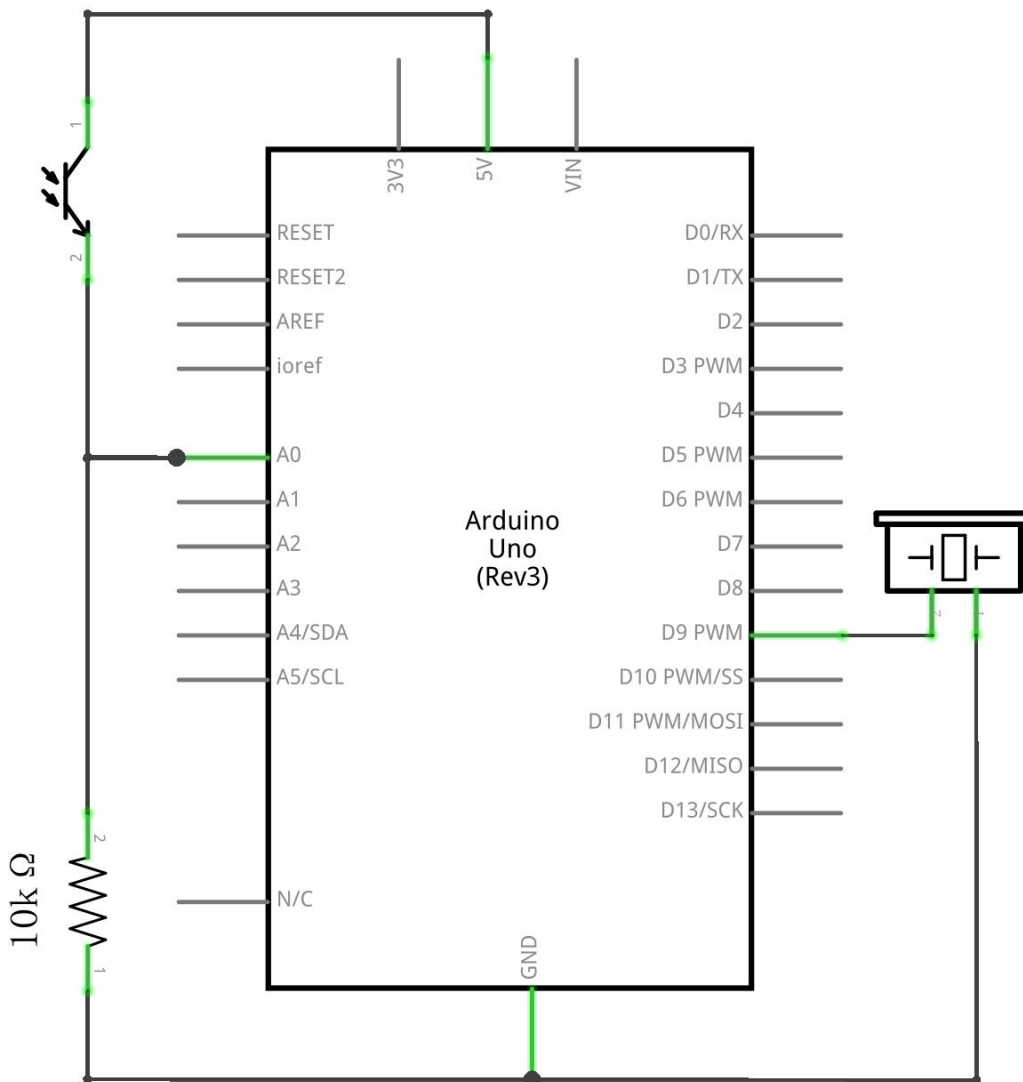

The shorter lead of the receiving triode is for negative, the other one for positive. Connect negative to 5V pin, positive to resistor; connect the other end of the resistor to GND, connect one end of a jumper wire to a clip which is electrically connected to sensor positive, the other end to analog pin. As shown below

When it's approaching a fire, the voltage value read from the analog port will differ. If you use a multimeter, you can see that when there is no fire approaching, the voltage it reads is around 0.3V; when there is fire approaching, the voltage it reads is around 1.0V. The nearer the fire is, the higher the voltage is.

So in the beginning of the program, you can initialize voltage value i (no fire value); Then, continuously read the analog voltage value j and obtain difference value $k=j-i$; compare k with 0.6V (123 in binary) to determine whether there is a fire approaching or not; if yes, the buzzer will buzz.

Connection Schematic

Wiring diagram

Lesson 24 Photocell

Overview

In this lesson, you will learn how to measure light intensity using an Analog Input. You will build on lesson 24 and use the level of light to control the number of LEDs to be lit.

The photocell is at the bottom of the breadboard, where the pot was above.

Component Required:

- (1) x KUONGSHUN UNO R3
- (1) x 830 tie-points breadboard
- (8) x leds
- (8) x 220 ohm resistors
- (1) x 1k ohm resistor
- (1) x 74hc595 IC
- (1) x Photoresistor (Photocell)
- (16) x M-M wires (Male to Male jumper wires)

Component Introduction

PHOTOCELL:

The photocell used is of a type called a light dependent resistor, sometimes called an LDR. As the name suggests, these components act just like a resistor, except that the resistance changes in response to how much light is falling on them.

This one has a resistance of about 50 k Ω in near darkness and 500 Ω in bright light. To convert this varying value of resistance into something we can measure on an UNO R3 board's analog input, it needs to be converted into a voltage.

The simplest way to do that is to combine it with a fixed resistor.

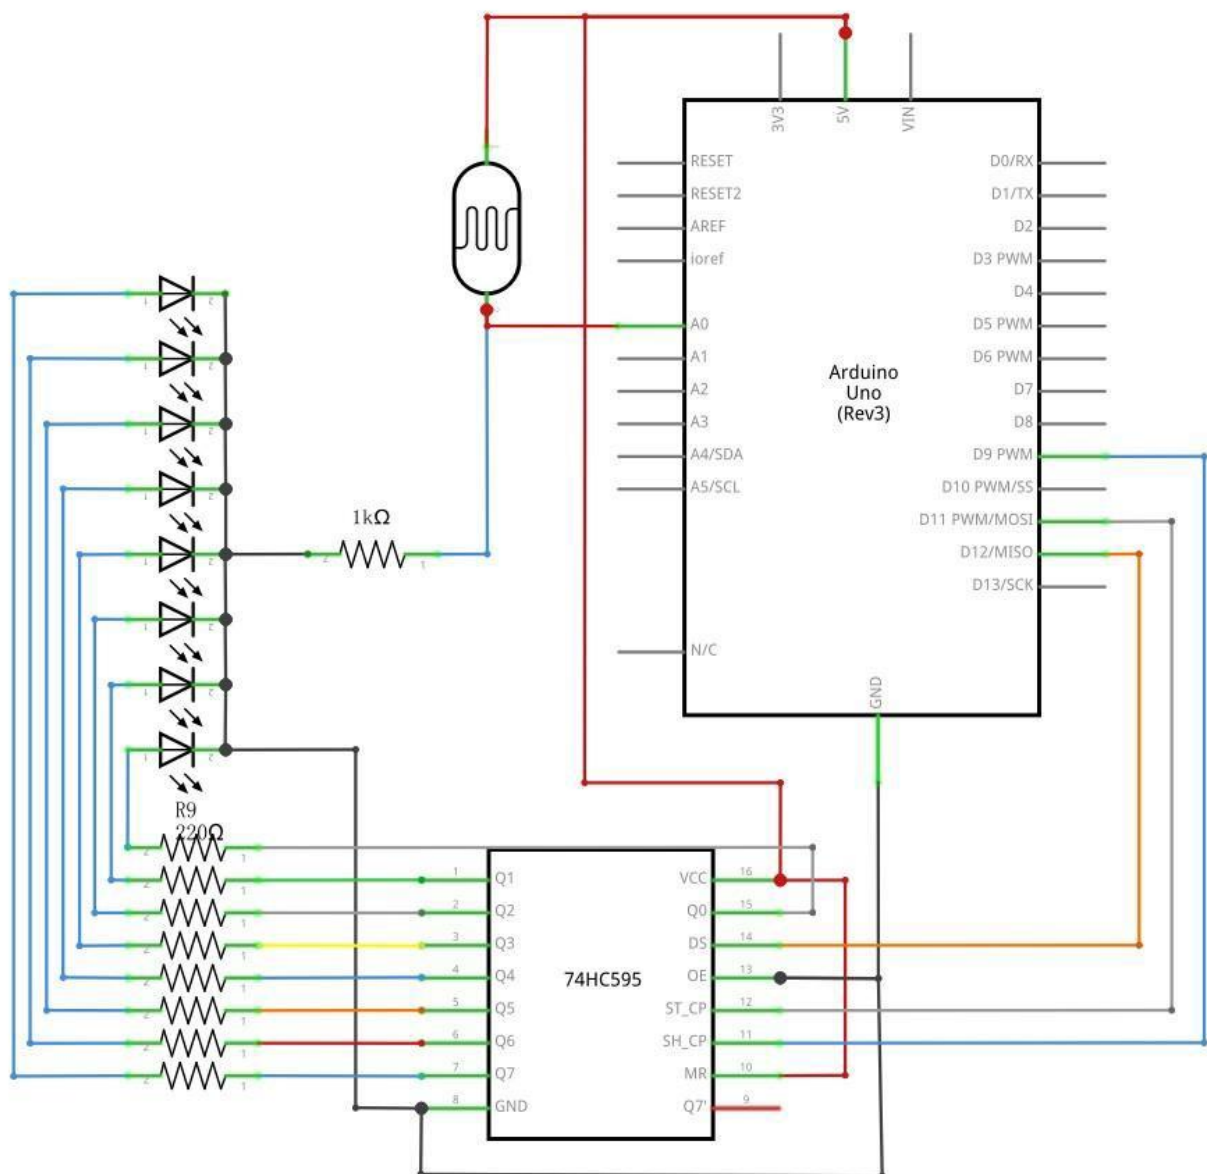

The resistor and photocell together behave like a pot. When the light is very bright, then the resistance of the photocell is very low compared with the fixed value resistor, and so it is as if the pot were turned to maximum.

When the photocell is in dull light, the resistance becomes greater than the fixed 1 kΩ resistor and it is as if the pot were being turned towards GND.

Load up the sketch given in the next section and try covering the photocell with your finger, and then holding it near a light source.

Connection Schematic

Wiring diagram

Code

After wiring, please open the program in the code folder- Lesson 26 Photocell and click UPLOAD to upload the program. See Lesson 2 for details about program uploading if there are any errors.

The first thing to note is that we have changed the name of the analog pin to be 'lightPin' rather than 'potPin' since we no longer have a pot connected.

The only other substantial change to the sketch is the line that calculates how many of the LEDs to light:

```
int numLEDsLit = reading / 57; // all LEDs lit at 1k
```

This time, we divide the raw reading by 57 rather than 114. In other words, we divide it by half as much as we did with the pot to split it into nine zones, from no LEDs lit to all eight lit. This extra factor is to account for the fixed 1 kΩ resistor. This means that when the photocell has a resistance of 1 kΩ (the same as the fixed resistor), the raw reading will be $1023 / 2 = 511$. This will equate to all the LEDs being lit and then a bit (numLEDsLit) will be 8.

Example picture

Lesson 25 74HC595 And Segment Display

Overview

After learning Lesson 24、25 and Lesson 26, we will use the 74HC595 shift register to control the segment display. The segment display will show number from 9-0.

Component Required:

- (1) x KUONGSHUN UNO R3
- (1) x 830 tie-points breadboard
- (1) x 74HC595 IC
- (1) x 1 Digit 7-Segment Display
- (8) x 220 ohm resistors
- (26) x M-M wires (Male to Male jumper wires)

Component Introduction

Seven segment display

Below is the seven-segment pin diagram.

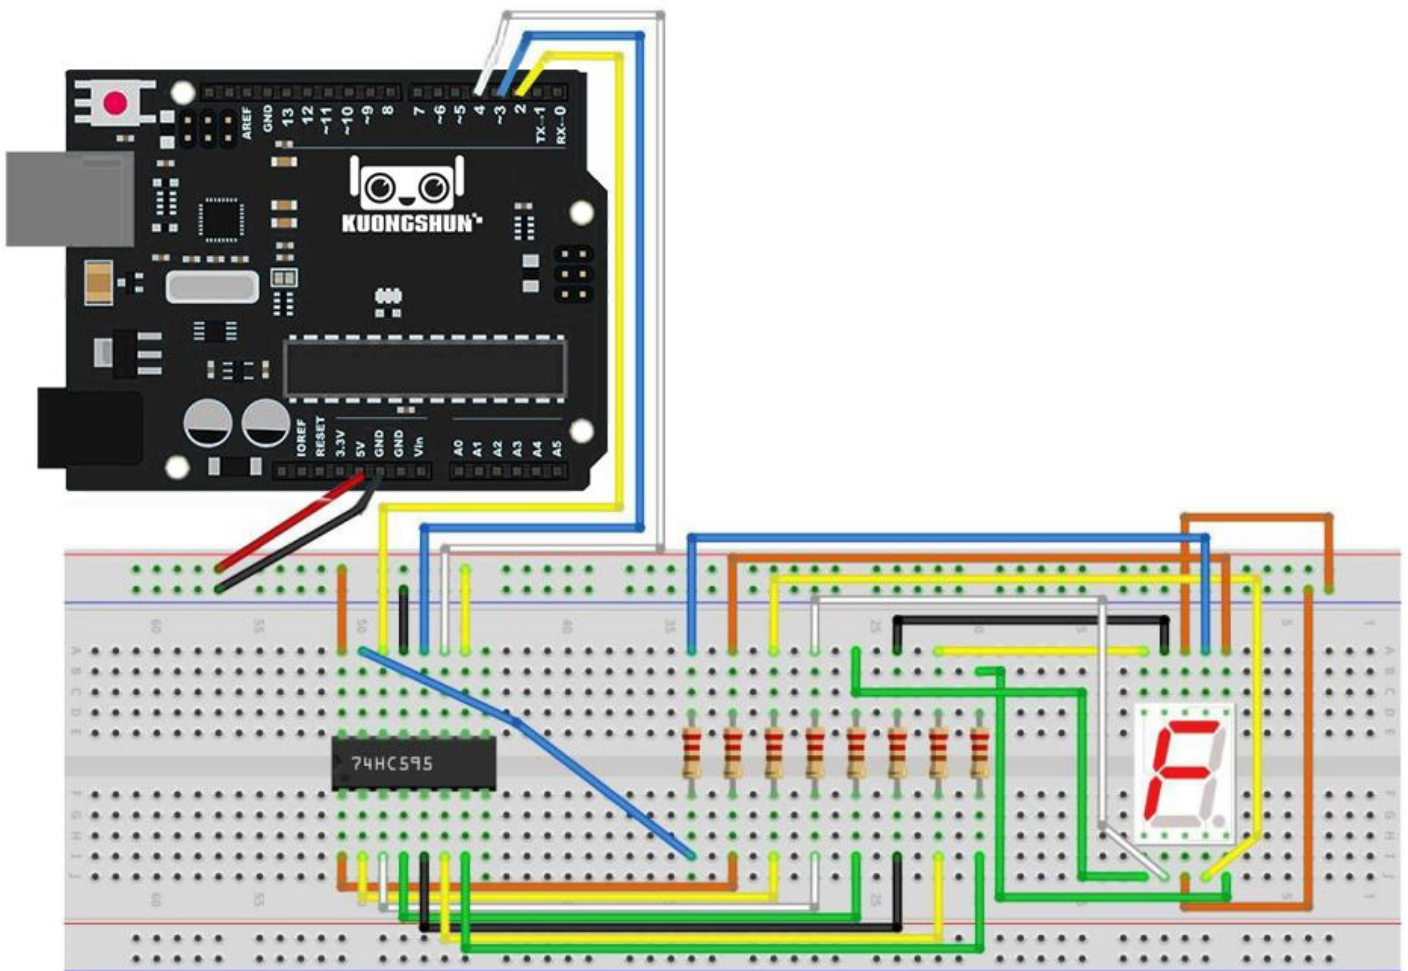

0-9 ten digits correspond with each segment are as follows (the following table applies common cathode seven segment display device, if you are using a common anode, the table should be replaced every 1 0 0 should all replaced by 1):

Displaydigital	dp	a	b	c	d	e	f	g
0	0	1	1	1	1	1	1	0
1	0	0	1	1	0	0	0	0
2	0	1	1	0	1	1	0	1
3	0	1	1	1	1	0	0	1
4	0	0	1	1	0	0	1	1
5	0	1	0	1	1	0	1	1
6	0	1	0	1	1	1	1	1
7	0	1	1	1	0	0	0	0
8	0	1	1	1	1	1	1	1
9	0	1	1	1	1	0	1	1

Connection Schematic

Wiring diagram

The following table shows the seven-segment display 74HC595 pin correspondence table:

74HC595 pin	Seven shows remarkable control pin (stroke)
Q0	7 (A)
Q1	6 (B)
Q2	4 (C)
Q3	2 (D)
Q4	1 (E)
Q5	9 (F)
Q6	10 (G)
Q7	5 (DP)

Step one: Connect 74HC595

First, the wiring is connected to power and ground: **VCC** (pin 16) and **MR** (pin 10) connected to 5V **GND** (pin 8) and **OE** (pin 13) to ground

Connection **DS**, **ST_CP** and **SH_CP** pin:

DS (pin 14) connected to UNO R3 board pin 2 (the figure below the yellow line) **ST_CP** (pin 12, latch pin) connected to UNO R3 board pin 3 (FIG blue line below) **SH_CP** (pin 11, clock pin) connected to UNO R3 board pin 4 (the figure below the white line)

Step two: Connect the seven segment display

The seven-segment display 3, 8 pin to UNO R3 board GND (This example uses the common cathode, if you use the common anode, please connect the 3, 8 pin to UNO R3 board + 5V)

According to the table above, connect the 74HC595 Q0 ~ Q7 to seven-segment display corresponding pin (A ~ G and DP), and then each foot in a 220 ohm resistor in series.

Code

After wiring, please open the program in the code folder- Lesson 27 74HC595 And Segment Display and click UPLOAD to upload the program. See Lesson 2 for details about program uploading if there are any errors.

Example picture

Lesson 26 Four Digital Seven Segment Display

Overview

In this lesson, you will learn how to use a 4-digit 7-segment display.

When using 1-digit 7-segment display, please notice that if it is common anode, the common anode pin connects to the power source; if it is common cathode, the common cathode pin connects to the GND.

When using 4-digit 7-segment display, the common anode or common cathode pin is used to control which digit is displayed. Even though there is only one digit working, the principle of Persistence of Vision enables you to see all numbers displayed because each the scanning speed is so fast that you hardly notice the intervals.

Component Required:

- (1) x KUONGSHUN UNO R3
- (1) x 830 tie-points breadboard
- (1) x 74HC595 IC
- (1) x 4 Digit 7-Segment Display
- (4) x 220 ohm resistors
- (23) x M-M wires (Male to Male jumper wires)

Lesson 27 Relay Module

Overview

In this experiment, we will learn how to use the 1 channel relay module.

Relay is a kind of component when the change of the input variables (incentive) to specified requirements, the output electric circuits of the charged amount occurs due to the step change of a kind of electrical appliances. This company produces the relay module can meet in 28 V to 240 V ac or dc power to control all kinds of other electric parts. MCU can be used to achieve the goal of timing control switch. Can be applied to guard against theft and alarm, toys, construction and other fields. Relay is an electrical control device. It has a control system (also called input circuit) and control system (also called the output circuit), the interaction between. Usually used in automatic control circuit, it is actually with a mall current to control large current operation of a kind of" automatics

Component Required:

- (1) x KUONGSHUN UNO R3
- (1) x Any electrically powered device such as a DC motor (This course uses DC motors as an example)
- (1) x 1 channel Relay module
- (3) x F-M wires (Female to Male jumper wires)
- (1) x F-F wires (Female to Female jumper wires)

Component Introduction

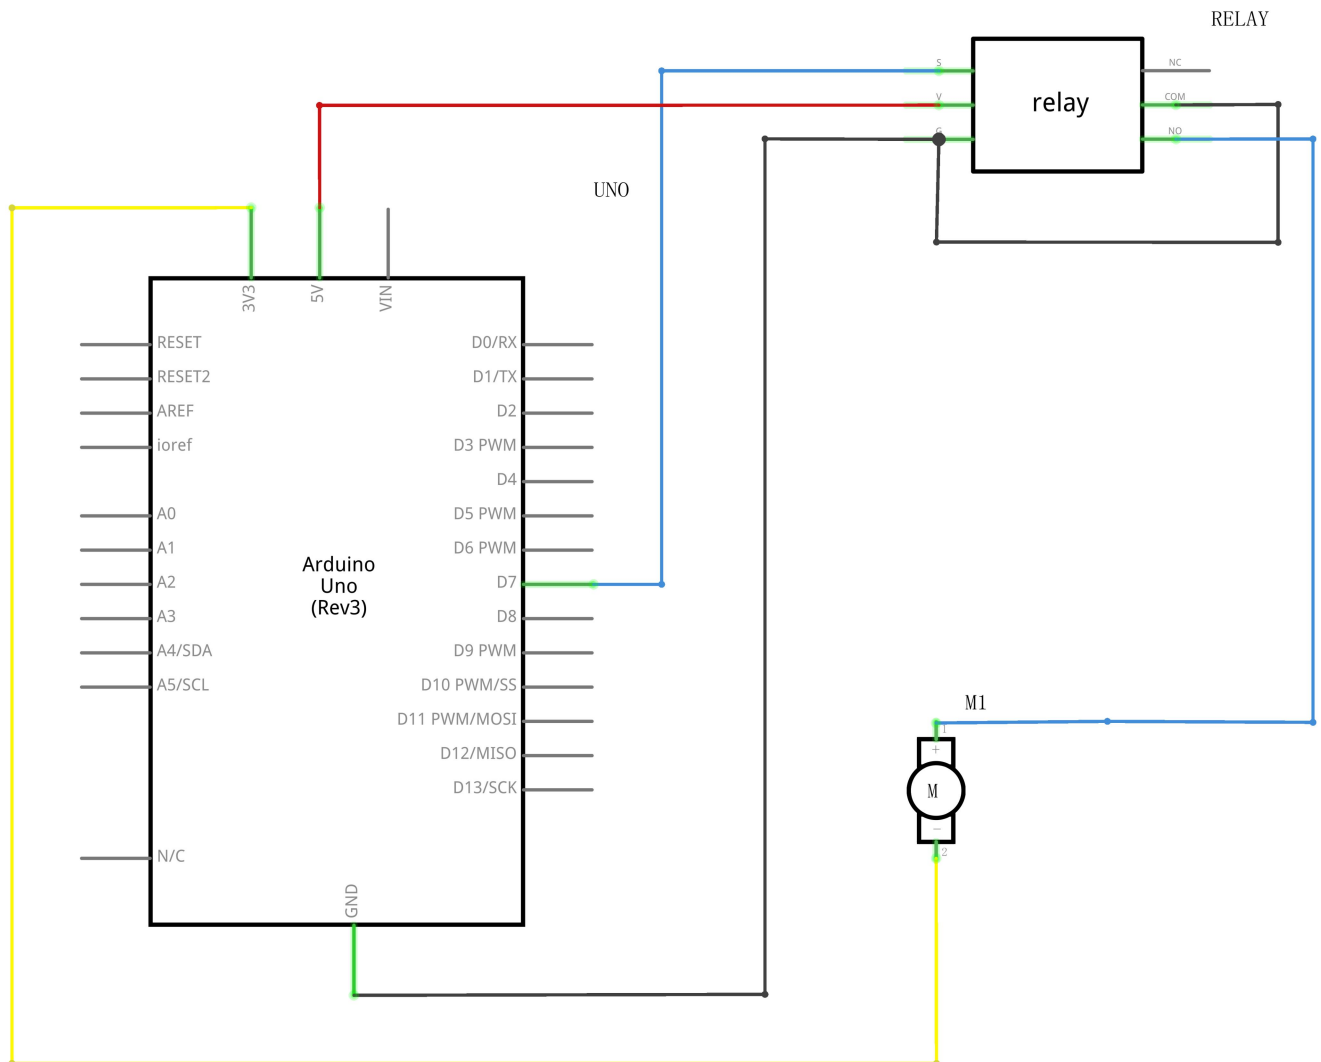

Relay:

A relay is an electrically operated switch. Many relays use an electromagnet to mechanically operate a switch, but other operating principles are also used as in solid-state relays. Relays are used where it is necessary to control a circuit by a low- power signal (with complete electrical isolation between control and controlled circuits), or where several circuits must be controlled by one signal. The first relays were used in long-distance telegraph circuits as amplifiers. They repeated the signal coming in from one circuit and re-transmitted it on another circuit. Relays were used extensively in telephone exchanges and early computers to perform logical operations.

A type of relay that can handle the high power required to directly control an electric motor or other loads is called a contactor. Solid-state relays control power circuits with no moving parts, instead using a semiconductor device to perform the switching. Relays with calibrated operating characteristics and sometimes multiple operating coils are used to protect electrical circuits from overload or faults. In modern electric power systems, these functions are performed by digital instruments called "protective relays".

We can use Arduino pin to control the relay module whether the current is on or not.

Connection Schematic

Wiring diagram

Code

After wiring, please open the program in the code folder- Lesson 30 Relay and click UPLOAD to upload the program. See Lesson 2 for details about program uploading if there are any errors.

After program loading, turn on all the power switches. The relay will pick up with a ringing sound. Then, the motor will rotate. After a period of time, the relay will be released, and the motor stops.

Example picture

Lesson 28 Stepper Motor

Overview

In this lesson, you will learn a fun and easy way to drive a stepper motor.

The stepper we are using comes with its own driver board making it easy to connect to our UNO.

Component Required:

- (1) x KUONGSHUN UNOR3
- (1) x 830 tie-points breadboard
- (1) x ULN2003 stepper motor driver module
- (1) x Stepper motor
- (1) x 9V1A Adapter (You can also connect the power cable to the uno board for power.)
- (1) x Power supply module (You can also connect the power cable to the uno board for power.)
- (6) x F-M wires (Female to Male DuPont wires)
- (1) x M-M wire (Male to Male jumper wire)

Component Introduction

Stepper

A stepper motor is an electro-mechanical device which converts electrical pulses into discrete mechanical movements. The shaft or spindle of a stepper motor rotates in discrete step increments when electrical command pulses are applied to it in the proper sequence. The motors rotation has several direct relationships to these applied input pulses. The sequence of the applied pulses is directly related to the direction of motor shafts rotation. The speed of the motor shafts rotation is directly related to the frequency of the input pulses and the length of rotation is directly related to the number of input pulses applied. One of the most significant advantages of a stepper motor is its ability to be accurately controlled in an open loop system. Open loop control means no feedback information about position is needed. This type of control eliminates the need for expensive sensing and feedback devices such as optical encoders. Your position is known simply by keeping track of the input step pulses.

Stepper motor 28BYJ-48 Parameters

- Model: 28BYJ-48
- Rated voltage: 5VDC
- Number of Phase: 4
- Speed Variation Ratio: 1/64
- Stride Angle: 5.625° /64
- Frequency: 100Hz
- DC resistance: 50Ω±7%(25°C)
- Idle In-traction Frequency: > 600Hz
- Idle Out-traction Frequency: > 1000Hz
- In-traction Torque >34.3mN.m(120Hz)
- Self-positioning Torque >34.3mN.m
- Friction torque: 600-1200 gf.cm
- Pull in torque: 300 gf.cm
- Insulated resistance >10MΩ(500V)
- Insulated electricity power: 600VAC/1mA/1s
- Insulation grade: A
- Rise in Temperature <40K(120Hz)
- Noise <35dB(120Hz,No load,10cm)

Interfacing circuits

WIRING DIAGRAM

The bipolar stepper motor usually has four wires coming out of it. Unlike unipolar steppers, bipolar steppers have no common center connection. They have two independent sets of coils instead. You can distinguish them from unipolar steppers by measuring the resistance between the wires. You should find two pairs of wires with equal resistance. If you've got the leads of your meter connected to two wires that are not connected (i.e. not attached to the same coil), you should see infinite resistance (or no continuity).

ULN2003 Driver Board

Product Description

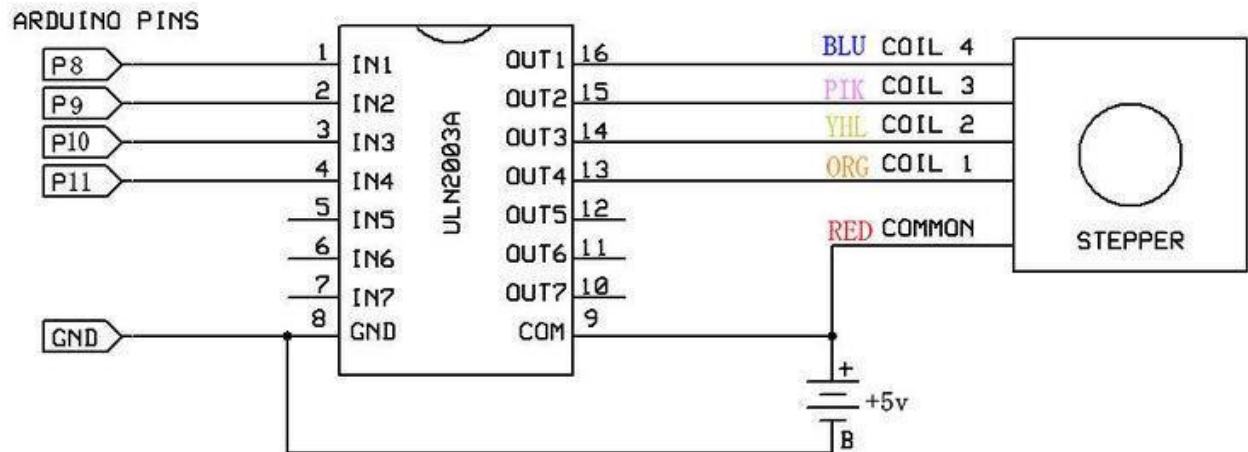

- Size: 42mmx30mm
- Use ULN2003 driver chip, 500mA
- A. B. C. D LED indicating the four phase stepper motor working condition.
- White jack is the four phase stepper motor standard jack.
- Power pins are separated
- We kept the rest pins of the ULN2003 chip for your further prototyping.

The simplest way of interfacing a unipolar stepper to Arduino is to use a breakout for ULN2003A transistor array chip. The ULN2003A contains seven Darlington transistor drivers and is somewhat like having seven TIP120 transistors all in one package. The ULN2003A can pass up to 500 mA per channel and has an internal voltage drop of about 1V when on. It also contains internal clamp diodes to dissipate voltage spikes when driving inductive loads. To control the stepper, apply voltage to each of the coils in a specific sequence.

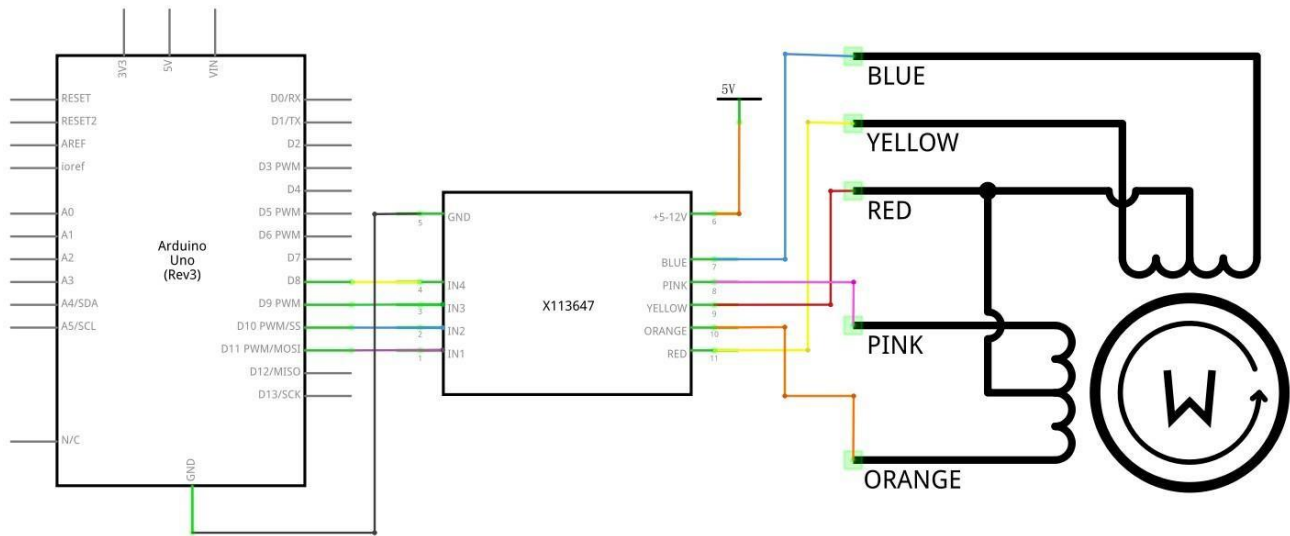

The sequence would go like this:

Lead Wire Color	---> CW Direction (1-2 Phase)							
	1	2	3	4	5	6	7	8
4 ORG	-	-						-
3 YEL		-	-	-				
2 PIK				-	-	-		
1 BLU						-	-	-

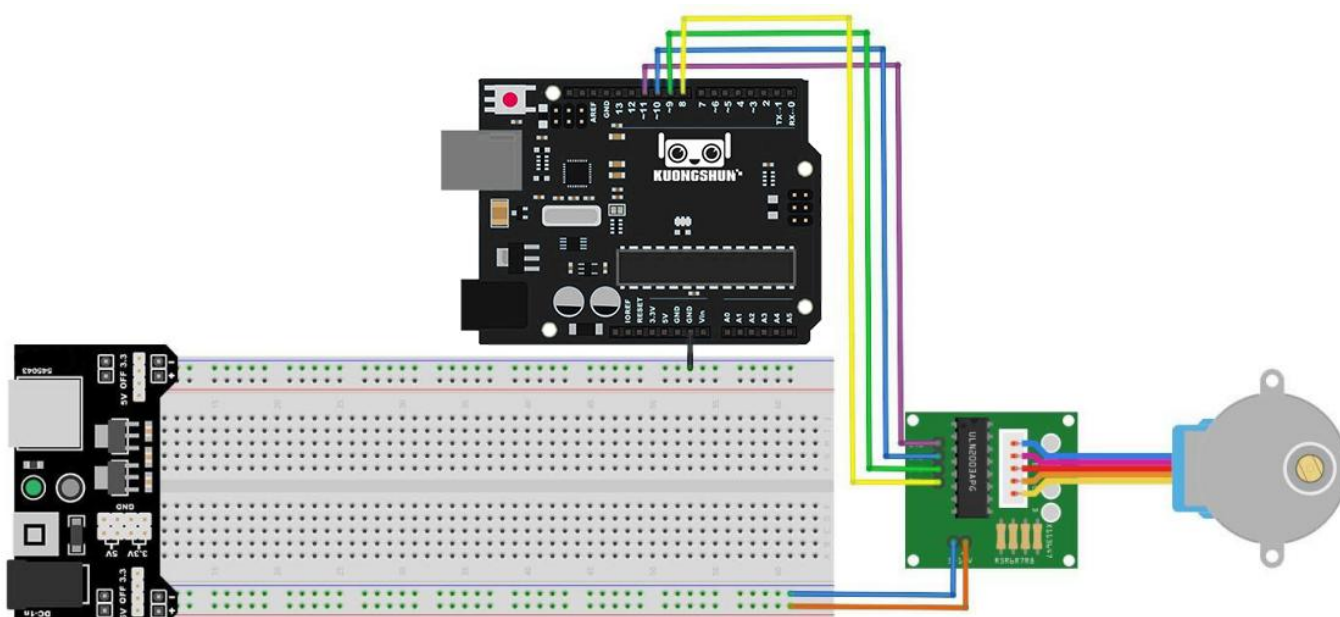

Here are schematics showing how to interface a unipolar stepper motor to four controller pins using a ULN2003A, and showing how to interface using four com

Connection Schematic

Wiring diagram

We are using 4 pins to control the Stepper. Pin 8-11 are controlling the Steppermotor.
We connect the Ground from to UNO to the Steppermotor.

Code

After wiring, please open the program in the code folder- Lesson 31 Stepper Motor and click UPLOAD to upload the program. See Lesson 2 for details about program uploading if there are any errors.

Before you can run this, make sure that you have installed the < Stepper > library or re-install it, if necessary. Otherwise, your code won't work.

For details about loading the library file, see Lesson 1.
